DTIC QUALITY INSPECTED 3

INTRODUCTION

The Air Force Office of Scientific Research Technical Report Summaries is published quarterly (March, June, September, and December). It contains a brief summary of each technical report received in the Technical Information Division and submitted to the Defense Technical Information Center (DTIC) for that quarter. Three indexes, subject, personal author and title are provided to help the user locate reports that may be of interest.

AFOSR does not maintain copies of technical reports for distribution. However, you may obtain any of these reports if you are registered with DTIC, by requesting the AD number of that report from the DTIC, Cameron Station, Alexandria, Virginia, 22314.

PURPOSE

The purpose of this report is to inform Air Force Laboratories about the science that the Air Force Office of Scientific Research is supporting.

AFOSR MISSION

The Air Force Office of Scientific Research (AFOSR) is the Single Manager of the Air Force Defense Research Sciences Program (Program Element 61102F) and the primary Air Force agency for the extramural support of fundamental scientific research. The AFOSR is organized under the Air Force Systems Command, DCS/Technology.

AFOSR awards grants and contracts for research in areas of science relevant to the needs of the Air Force. Research is selected for support from proposals received in response to the Broad Agency Announcement originating from scientists investigating problems involving the search for new knowledge and the expansion of scientific principles. Selection is on the basis of scientific potential for improving Air Force operational capabilities, originality, significance to science, the qualification of the principal investigators, and the reasonableness of the proposed budget.

KEY TO READING THE DATA

The summaries consist of three indexes and the abstracts. From one of the indexes, locate the AD number of the report that is of interest to you. Use this number to locate the abstract of the report in the abstracts section. The first report submitted to DTIC during the quarter (the one with the lowest AD number) appears on the last page of the abstracts section. The last report submitted to DTIC during the quarter (the one with the highest DTIC number) appears on the first page of the abstracts section. The following terms will give you a brief description of the elements used in each summary of this report.

DTIC Report Bibliography - DTIC's brief description of a technical report.

Search Control Number - A number assigned by DTIC at the time a bibliography is printed.

AD Number - A number assigned to each technical report when received by the DTIC.

Field & Group Numbers - (appearing after the AD number) First number is the subject field, and the second number is the particular group under that subject field.

Corporate Author/Performing Organization - The organization; e.g., college/university, company, etc., at which the research is conducted.

Title - The title of the technical report.

Descriptive Note - Gives the type of report; e.g., final, interim, etc., and the period of the time of the research.

Date - Date of the technical report.

Pages - Total number of pages contained in the technical report.

Personal Author - Person or persons who wrote the report.

Contract/Grant Number - The instrument control number identifying the contracting activity and funding year under which the research is initiated.

Project Number - A number unique to a particular area of science; e.g., 2304 is the project number for mathematics.

Task Number - An alphanumeric number unique to a specific field of the main area of science; e.g., 2304 is the project number for mathematics and A3 is the task number for computational sciences.

Monitor Number - The number assigned to a particular report by the government agency monitoring the research. The number consists of the government monitor acronym, the present calendar year and the technical report assigned consecutively; e.g., AFOSR-TR-83-0001 is the first number used for the first technical report processed for Calendar Year 1983.

Supplementary Note - A variety of statements pertaining to a report. For example, if the report is a journal article, the supplementary note might give you the journal citation, which will include the name of the journal the article it appears in, and the volume number, date, and the page numbers of the journal.

Abstract - A brief summary describing the research of the report.

Descriptors - Key words describing the research.

Identifiers - Commonly used designators, such as names of equipment, names of projects or acronyms, the AFOSR project and task number, and the Air Force Research Program Element number.

*BARBITURATES

Reprint: Inhibition of Cell Division in Hepatoma Cell Cultures by Chloroacetic and Carbon Tetrachloride Combination.
AD-A247 241

*BEHAVIOR

Stress-Induced Enhancement of the Startle Reflex.*
AD-A247 096

*BIOCHEMISTRY

Biochemical Mechanisms Controlling Bioactivity of Adrenal Chromaffin Cells.*
AD-A247 160

*BIOLOGICAL RHYTHMS

Study of SCN Neurochemistry Using In Vivo Microdialysis in the Conscious Brain: Correlation with Overt Circadian Rhythms.*
AD-A247 172

*BIOLOGY

Reprint: Comparison of Estimates of Effects of a Complex Effluent at Differing Levels of Biological Organization.
AD-A247 217

*BIOSYNTHESIS

Reprint: Biosynthesis and Biotransformation of Glutathione S-Conjugates to Toxic Metabolites.
AD-A247 215
Reprint: Inhibition of Rat Kidney Mitochondrial DNA, RNA and Protein Synthesis by Halogenated Cysteine S-Conjugates.
AD-A247 357

*BOUNDARY LAYER FLOW

Steady and Transient Analysis of Flows Exhibiting Strong Viscous/Inviscid Interaction (Composite RNS Procedures).
AD-A247 171

*BRAIN

Measurement and Regulation of Central Noradrenergic Neurotransmission.*
AD-A247 044

Locus Coeruleus, Vigilance and Stress: Brain Mechanism of Adaptive Behavioral Responsiveness.*
AD-A247 080

Stress-Induced Enhancement of the Startle Reflex.*
AD-A247 096

The Coordinated Noninvasive Studies (CNS) Project. Phase 1.*
AD-A247 159

*BRAIN DAMAGE

Neuropsychological Components of Object Identification.*
AD-A247 049

*CANCER

Reprint: Chemical, Oncogenic and Growth Factor Inhibition of Gap Junctional Intercellular Communication: An Integrative Hypothesis of Carcinogenesis.
AD-A248 972

*CARBON

Reprint: Shock Tube Measurements of the Reactions of CN with O and O₂.
AD-A248 930

Fundamental Studies of Carbon, NH₃, and Oxygen Rings and Other High Energy Density Molecular Systems.*
AD-A248 983

Reprint: A Shock Tube Study of Reactions of C Atoms and CH with NO Including Product Channel Measurements.
AD-A248 978

Reprint: High Temperature Shock Tube Study of Reactions of CH and C-Atoms with N₂.
AD-A247 076

Reprint: A Shock Tube Study of H + HNCY Yields NH₂ + CO.
AD-A247 086

*CARBON MONOXIDE

Reprint: A Shock Tube Study of H + HNCY Yields NH₂ + CO.
AD-A247 086

*CARCINOGENESIS

Reprint: Chemical, Oncogenic and Growth Factor Inhibition of Gap Junctional Intercellular Communication: An Integrative Hypothesis of Carcinogenesis.
AD-A248 972

Reprint: Chemical, Oncogenic and Growth Regulator Modulation of Extracellular, Intracellular and Intercellular Communication.
AD-A247 675

*CARCINOGENS

Reprint: Inhibition of Rat Kidney Mitochondrial DNA, RNA and Protein Synthesis by Halogenated Cysteine S-Conjugates.
AD-A247 357

*CATIONS

Excited Negative Ions and Molecules and Negative Ion Production.*
AD-A247 017

Theoretical/Experimental Investigations of the Structure and Dynamics of Highly Energetic Dication Species.*
AD-A247 050

*CELL DIVISION

Reprint: Inhibition of Cell Division in Hepatoma Cell Cultures by Chloroacetic and Carbon Tetrachloride Combination.
AD-A247 241

*CELLS

Reprint: Effects of Specific Monooxygenase and Oxidase Inhibitors on the Activation of 2-Aminofluorene by Plant Cells.
AD-A247 242

*CELLS (BIOLOGY)

Reprint: Chemical, Oncogenic and

ABSTRACT: (U) This document includes the detailed
results of studies to determine the efficacy of using a
Laser-Pumped-Kerr-Liquid-Filled-Hollow-Fiber technique to
generate a superbroad band multiwavelength coherent light
source. This technique has been demonstrated to be
effective at a range of wavelengths from the near IR to
the near UV. The present design is conceptually simple,
of low cost and is amenable to space based applications
including Lidar. The Phase I effort has centered upon
obtaining a more fundamental understanding of the
phenomena and determining the operational characteristics
of the present design. The research work involved the use
of different Kerr liquid media, focusing arrangements
and fiber geometries. In addition, a major part of the
work involved using different pump laser sources to
explore the effect of different frequencies, pulse widths
and spectral line-widths. The design is expected to be
vastly improved with continued development. The specific
recommendations from the research team include (1)

ABSTRACT: (U) Very early in this project we fabricated several magnets of the composition Pr15Fe7986 of small sizes, typically 4 mm in diameter and 10 mm long. Praseodymium-based magnets behave as well as the neodymium based magnets at room temperature and above. However, unlike neodymium based magnets, their praseodymium counterparts exhibit significantly better magnetic properties at cryogenic temperature. Therefore, we proposed to focus our efforts in the development of Pr-Fe-B-based magnets. Permanent magnets were fabricated following a routine powder metallurgical technique. Since larger size magnets are needed for the construction of devices, we had to improve our experimental facilities. A large three-zone furnace together with a large sample chamber (approximately 5 inches in diameter) was assembled. This was needed for the sintering and post-sintering treatments of the magnets.

UNCLASSIFIED REPORT

ABSTRACT: (U) This Final Technical Report describes completed research accomplishments and ongoing activities that are focused on the evolution of boundary driven acoustic disturbances in a low Mach number shear flow like that found in the chamber of a solid rocket engine. The completed work (manuscripts in Appendices A and B) focuses on the relatively complex wave systems that appear in a two-dimensional planar shear flow following the refraction of very simple, initially planar axial disturbances. Work in progress emphasizes: (1) the characteristics of acoustic disturbances driven by sidewall mass addition in semi-confined channels and tubes, (2) the role of strongly injected Stokes boundary layers in providing a transition from the acoustic flow to the no-slip condition on the wall, and (3) mathematical methods required to deal with nonlinear processes within an acoustically disturbed flow. The review of our work emphasizes the importance of studying the evolution of boundary driven acoustic disturbances, primarily to gain an understanding of how small burning rate transients (modelled by unsteady wall injection) lead to large engine chamber responses observed in unstable solid rockets.

UNCLASSIFIED REPORT

ABSTRACT: (U) During the second year of this effort, we focused on introducing the effect of combustion in the computation of the spatially, developing shear layer, and continued our analysis of the effect of density variation and upstream forcing on the growth of the mixing zone of the shear layer. We have developed a flame sheet model for the simulation of combustion at high Damkohler numbers where the application of the transport element method proves to be rather expensive. The model uses the instantaneous local strain rate as an input from the flow computation and, by integrating a one dimensional equation, computes the rate of burning within each flamelet within the domain. Numerical, Simulation, Turbulent, Combustion, Vortex, Methods.

UNCLASSIFIED REPORT

ABSTRACT: (U) This is the final technical report for grant AFOSR-89-0147 entitled HIGH-RESOLUTION MICROWAVE OBSERVATIONS OF SOLAR ACTIVITY. This report covers the period from 01 November 1988 to 30 April 1992. It contains the abstracts for twenty four (24) presentations at professional meetings (Section II); and reprints of seventeen (17) papers (Section IV). The twenty four (24) professional presentations included meetings of the American Astronomical Society (AAS), the American Geophysical Union (AGU), the Committee on Space Research (COSPAR), the International Astronomical Union (IAU), and the Union Radio Scientifique Internationale (URSI). The Very Large Array (VLA) and the Arecibo Observatory are the world's largest radio telescopes, each operated at enormous expense by the National Science Foundation (NSF); the twenty one (21) successful proposals with these facilities, totaling fifty one (51) days, therefore represent an extremely efficient method of carrying out research by the Air Force Office of Scientific Research (AFOSR) that essentially funds salaries for Tufts scientists who use these facilities, analyze the data, and publish the results. Sun: eruptions, flares, origin and prediction of solar activity; Radio emission from coronal loops and filaments; Resolution of the pre-flare, impulsive and decay phases of solar flares; X-ray emission from coronal loops and flares; Solar Maximum Mission satellite; NASA balloon flights of high-energy

UNCLASSIFIED REPORT

ABSTRACT: (U) To summarize, progress has been made on a family of related problems, including: A model of endstopped visual cortical neurons was extended to include complex components; An extensive simulation of the model was completed with regard to orientation, positional, spatial frequency, curvature, chevron, and end-line sensitivity; Orientation discontinuities were extended into the motion domain, and psychological and computational experiments were performed to confirm the hypothesis of multiple directions being represented at a point of discontinuity; A theory was developed to capture the non-linearities necessary for early measurement of orientation and curvature; A totally different theory has begun to take shape for functionally characterizing cytochrome oxidase blobs; and The mathematical foundations were laid for a theory of shape.

ABSTRACT: (U) Patterns of 40 to 80 Hz oscillation have been observed by researchers of this laboratory in the large scale activity not only of olfactory cortex, but also visual neocortex, and shown to predict the olfactory and visual pattern recognition responses of a trained animal. Similar observations of 40 Hz oscillation in auditory and motor cortex, and in the retina and EMG have been reported. It thus appears that cortical computation in general may occur by dynamical interaction of resonant modes, as we have long thought to be the case in the olfactory system. The oscillation can serve a macroscopic clocking function and entrain or 'bind' the relevant microscopic activity of disparate cortical regions into a well defined phase coherent collective state of 'gestalt'. This can override irrelevant microscopic activity and produce coordinated motor output. We have further evidence that the oscillatory activity is roughly periodic, but actually appears to be chaotic (nonperiodic) when examined in detail.

ABSTRACT: (U) The Section Conference was a success and the information presented by the speakers was acknowledged by the attendees. COSPAR was established to continue the cooperative programs of rocket and satellite research successfully undertaken during the International Geophysical Year of 1957-58. The ISCU resolution creating COSPAR stated that the primary purpose of COSPAR was to provide the world scientific community with the means whereby it may exploit the possibilities of satellites and space probes of all kinds for scientific purposes, and exchange and resulting data on a cooperative basis. The objective of the AFOSR supported AIBS project was to provide for travel and subsistence support for a limited number of US speakers to attend Section MF.4 Combined Effect: Radiation, Microgravity, Trauma and Other Factors at the XXVIIIth meeting of COSPAR held at The Hague, The Netherlands, 25 June - 7 July 1990.

UNCLASSIFIED REPORT

ABSTRACT: (U) The oxidation of trichloroethylene (TCE) by toluene dioxygenase in vivo and in vitro has been investigated. In a previous study, the initial rate of TCE oxidation by *Pseudomonas putida* F1 declined rapidly. This was shown in vivo, in the present study, to be due to toluene dioxygenase-dependent activation of TCE to produce reactive intermediates. Carbon-14 label from metabolism of radioactive TCE was incorporated into proteins, small molecules, DNA, RNA, and lipid. Alkylation of proteins, including toluene dioxygenase, caused metabolic poisoning and the loss of TCE-degrading ability. *P. putida* was able to recover from TCE-mediated cytotoxicity. Toluene dioxygenase enzyme components were purified from recombinant *E. coli* strains by the use of conventional chromatographic methods. The major products of TCE oxidation by purified toluene dioxygenase have been identified as formic acid and glyoxylic acid. An additional minor product was shown to result from the alkylation of reduced pyridine dinucleotide (NADPH) by a reactive TCE intermediate generated by the toluene dioxygenase catalyzed reaction. Experiments with 14C-TCE showed that enzyme inactivation was due to non-specific alkylation of the proteins by diffusible reactive intermediates. A recombinant *E. coli* expressing cloned toluene dioxygenase genes oxidized TCE. The rate of TCE oxidation by the *E. coli* strain was slower than that of *P.*

UNCLASSIFIED

PAGE

8

T85004

putida F1 but the rates were sustained for a longer time. The use of recombinant strains or gratuitously induced *P. putida* F1 could have important implications for bioremediation. Furthermore, a greater understanding of the mechanism of toluene dioxygenase inactivation will be crucial for developing optimum systems for TCE-biotreatment.

ABSTRACT: (U) The studies demonstrated that the injection of synapsin I, in addition to reducing the background spontaneous release of transmitter, produces a reduction of transmitter released by direct depolarization of the presynaptic terminal. Furthermore the spontaneous release mimics the time course of the reduction of the evoked release such that the two can be easily correlated. The effect of CaM kinase II injection produces an increased miniature frequency in parallel with the increase in evoked release without changing the time course of the miniatures. This indicated the probability of release was being enhanced both during spontaneous and evoked release, only increasing the likelihood of vesicular release. A similar type of calcium channel is also present for peptide secretion from the hypothalamus to the hypophysis.

ABSTRACT: (U) Ever since our awareness of the biological health hazards of increased radiation and chemical exposure became heightened, a tremendous amount of human scientific effort and societies' resources have been directed towards understanding the basic causes of the wide variety of diseases induced by these agents. While it is fair to say that much valuable information on the mechanisms by which radiation and chemicals can induce birth defects, cancers, reproductive dysfunction, neurotoxicities, and other acute and chronic diseases has been produced, our understanding is far from complete. A dilemma has been created by the practical problem of having to make difficult decisions on the use of chemical and radiation-generating technologies, in all aspects of modern life, with incomplete knowledge. These decisions to produce and use or not to produce and use chemicals must include information pertaining not only to the potential deleterious health and environmental consequences of their use but also to the potential deleterious health and environmental, as well as economic and esthetic consequences, if they are not used. To help narrow this immense problem, this paper will focus on cancer risks (although it should be apparent, subsequently, that much of this analysis has relevance to

DTIC REPORT BIBLIOGRAPHY

birth defects and other chronic diseases). The objective will be to challenge the current paradigm shaping much of the scientific community's and, therefore, the government's regulatory units' view of carcinogenesis.

ABSTRACT: (U) That rather self-serving quotation from Albert Szent-Gyorgyi was chosen to highlight this brief analysis of the problem of understanding the elements of a biologically based cancer risk-assessment model. It should go without saying that understanding all the mechanisms related to multistep carcinogenesis is not an easy task. The known complex interactions of genetic, developmental, sex, dietary, and environmental factors in carcinogenesis in both laboratory animals and human beings precludes direct and easy extrapolation from controlled in vitro and experimental animal bioassay systems to the uncontrolled human situation. While recent advances in modern molecular biology related to development of the concept of oncogenes, cancer suppressor genes, experimental initiation/promotion/progression model systems, and basic studies on the control of cell growth (i.e., growth regulators and second messengers) have given us valuable information related to the cancer process, no clear picture or consensus view has emerged. For the sake of taking a different view of the information gathered, we will challenge some of the basic assumptions related to the

current paradigm guiding the cancer research field, namely, 'carcinogenesis as mutagenesis'. Put succinctly, while the bulk of the molecular, biochemical, and cellular studies related to 'carcinogens' and carcinogenesis have been done on the predominate cells of target organs the target cell for carcinogenesis (i.e., the early stem or progenitor cell) has not been used.

ABSTRACT: (U) In November 1990, the CAIP Center of Rutgers University organized and hosted a workshop on Neural Networks. The workshop attracted over 120 leaders in the field from the United States and abroad. The goal of the workshop was to assess the current state-of-the-art Neural Network architecture and algorithms and to consider the most promising directions for further research in this rapidly developing field. A book was printed as an outgrowth of the workshop and constitutes a collection of some of the important papers presented and discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) The two-year project to study the dynamics of the leading-edge vortex (LEV) over a pitching airfoil under conditions of dynamic stall, was started in January 1990. Several accomplishments have been made during these two years. The most significant of these are (1) the construction of a special water channel suitable for the study of dynamic stall over a pitching airfoil, (2) the measurement of surface pressure distributions over the airfoil under several key operating conditions, and (3) development of the techniques of Particle Image Velocimetry (PIV) and its use in the measurement of instantaneous velocity and vorticity field in the two-dimensional flow around the airfoil. Some of these data which are the first of their kind have been used to understand the physics of unsteady vorticity dynamics over a pitching airfoil. These data are being made available to other investigators for use as database in validating their numerical models. Unsteady Aerodynamics, Dynamic Stall, Supermaneuverability, Vortex Dynamics.

ABSTRACT: (U) As in the prior material, the largest population of neurons in the Human SCN contains NT. These are distributed throughout the nucleus and are accompanied by a dense axonal plexus which is probably intrinsic. The NT plexus is uniformly dense throughout the SCN with numerous, small varicosities. These are distributed in a pattern that indicates the synapses are predominantly axodendritic. The second largest population of neurons is VP-containing. These also are widely distributed but perikarya are not present in the ventral-medial portion of the nucleus. The VP plexus is also dense and the distribution of axons also indicates a predominantly axodendritic synapse organization. NPY-containing neurons are found predominantly in the central part of the SCN. There is a dense, and quite coarse, plexus of varicosities and axons peripherally with many fewer axons in the area of NPY cell bodies. The plexus includes a set of very fine fibers and varicosities that presumably arise either from the SCN neurons or the lateral geniculate. VIP perikarya are located very ventrally and medially in the nucleus. Axons project through the nucleus and out into the adjacent inferior hypothalamus. The area innervated by these VIP fibers appears much wider than in the rat and includes the paraventricular nucleus.

ABSTRACT: (U) After returning from CAPE we were busy installing the SUN workstations, disks, Exabyte tape readers, etc., so as to be compatible for NCAR radar analysis software. We were also busy installing software to read the PMS data tapes from the Wyoming and NCAR King Ahrs. While the Wyoming aircraft data is on the NCAR mass store, the NCAR data is still in the process of transfer to mass store. We are still to install software to read the T-28 aircraft tapes. We spent substantial time in validating and calibrating the CP-2 multiparameter radar data. Time series data from 24 August 1991 was evaluated in detail by myself and Ms. Li Liu a Ph.D. graduate student partially supported by this project. We chose time series data for evaluation since we have better handle on such data. We are pleased with the data quality from CP-2. We have chosen the cases from 26, 28 July and 5, 8, 9 August for in-depth analysis.

ABSTRACT: (U) The metabolism and cytotoxicity of benzyl 1,2,3,4-pentachlorobuta-1,3-dienyl sulfide (1) and benzyl 2-chloro-1,1,2-trifluoroethyl sulfide (2) were studied as an alternative test of the hypothesis that the toxicity of the cysteine S-conjugates S-(pentachlorobutadienyl)-L-cysteine and S-(2-chloro-1,1,2-trifluoroethyl)-L-cysteine is associated with their metabolism to unstable thiols; the expectation was that the benzyl sulfides 1 and 2 would undergo cytochrome P-450 dependent benzylic hydroxylation and that the intermediate hemimercaptals would eliminate unstable, cytotoxic thiols. This expectation was realized: 1 and 2 were cytotoxic in isolated rat hepatocytes. The cytotoxicity of 1 was greater in hepatocytes from phenobarbital-treated rats compared with control rats and in male than in female rats and was inhibited by carbon monoxide and 2-(N,N-diethylamino)ethyl 2,2-diphenylvalerate HCl (SKF 525-A). Benzyl sulfides 1 and 2 were metabolized to benzaldehyde by rat hepatic microsomal fractions and by a purified, reconstituted cytochrome P-450PB-8 system. Benzaldehyde was not cytotoxic. These results provide support for the

AD-A247 358

UNCLASSIFIED

PAGE 17

T85004

hypothesis that benzyl sulfides 1 and 2 and the corresponding cysteine S-conjugates yield unstable thiols, which may give rise to acylating agents or to stable, but toxic, terminal products that are responsible for the cytotoxic effects of the benzyl sulfides and cysteine S-conjugates.

ABSTRACT: (U) The glutathione-dependent metabolism of the nephrotoxin and nephrocarcinogen hexachloro-1,3-butadiene (HCB) was investigated in subcellular fractions from rat liver and kidney. HCB was metabolized by hepatic glutathione S-transferases to (E)- and (Z)-1-(glutathion-S-yl)-pentachlorobuta-1,3-diene (GPCB) in a ratio of 20:1, which were identified by secondary ion MS and by GC-MS after acid hydrolysis. The formation of GPCB was dependent on time and on protein and glutathione concentrations. Microsomal glutathione S-transferases from rat liver catalyzed GPCB formation more efficiently than did cytosolic glutathione S-transferases; very low rates of GPCB formation were observed in kidney subcellular fractions. GPCB is also a substrate for glutathione S-transferases and is metabolized to a diglutathione conjugate, which was identified by secondary ion MS and 13C NMR spectrometry as 1,4-bis(glutathion-S-yl)-1,2,3,4-tetrachlorobuta-1,3-diene (BTCB). BTCB formation from GPCB was dependent on time and on protein, glutathione, and GPCB concentrations. Hepatic cytosol catalyzed BTCB formation more efficiently

than did hepatic microsomes; significant amounts of B7CB were also formed in kidney cytosol. Hepatic formation of glutathione S-conjugates, translocation of the S-conjugates to the kidney, and renal processing to form reactive intermediates may be the cause of HCBD-induced nephrotoxicity and, perhaps, nephrocarcinogenicity. The halogenated olefin HCBD is a selective nephrotoxin and a potent nephrocarcinogen. (Author)

ABSTRACT: (U) The mutagenicity of benzyl 1,2,3,4,4-pentachlorobutadienyl sulfide (BPBS) and benzyl 1,2-dichlorovinyl sulfide (BDVS) was studied in the Ames preincubation assay to investigate the hypothesis that the mutagenic effect of the cysteine S-conjugates S-(pentachlorobutadienyl)-L-cysteine and S-(1,2-dichlorovinyl)-L-cysteine is associated with their metabolism to unstable thiols. Under conditions enabling cytochrome P-450-dependent benzylic hydroxylation of BPBS and BDVS, both benzyl sulfides were mutagenic. Thus results in combination with the lack of mutagenicity observed with benzaldehyde and with the tert-butyl analogues, which cannot be metabolized to a hemimercaptal, indicate that the formation of unstable thiols is responsible for the mutagenic effects of the benzyl sulfides and the corresponding cysteine S-conjugates. Benzyl 2-chloro-1,1,2-trifluoroethyl sulfide, which also undergoes benzylic hydroxylation, was negative in the Ames-Test; this is in agreement with the observed lack of mutagenicity of the corresponding S-conjugate S-(2-chloro-1,1,2-trifluoroethyl)-L-cysteine. Also, benzyl 2-chloroethyl sulfide, which, along with the corresponding S-conjugate S-(2-chloroethyl)-L-cysteine, does not require bioactivation, was a potent, direct-acting

ASTM STP 1115, p287-298 1991. Available only to DTIC
users. No copies furnished by NTIS.

ABSTRACT: (U) Plant activation is the process by which
promutagenic agents are activated into mutagens by plant
systems. Many promutagens are activated by plants as well
as by the familiar mammalian microsomal monooxygenase
systems. However, several environmentally important
agents are preferentially activated by plant cells.
Plants have become a reservoir for the deposition and
accumulation of environmental xenobiotics. With the
widespread use of agricultural chemicals on crop plants
and with the global exposure of plants to pollutants, the
possibility that plant-activated agents may be introduced
into the human food chain is a cause of concern.
Environmentally relevant agents should be evaluated with
plant assays. The plant cell/microbe coinoculation assay
uses cultured plant cell suspensions as the activating
system and bacteria or yeast cells as the genetic
indicator organism. After a treatment time, the microbes
are plated on selective medium. In this way the
activation system and the genetic system can be
independently studied. In addition, the viability of the
plant cells and the microbial cells can be independently
determined so that the toxicity of a test agent can be
evaluated. We have employed cultured tobacco, cotton,
carrot, maize, and tradescantia cells to study the

ABSTRACT: (U) The modulation of gap junctional intercellular communication (GJIC) plays an important role during tumor promotion. Several tumor-promoting agents are known to inhibit this form of cellular coupling. In addition, tumor cells and cells expressing certain oncogenic products have been shown to exhibit inhibited or reduced GJIC. The Ha-ras oncogene is expressed in a wide variety of human tumors from different tissues. Its p21 product is a membrane-bound polypeptide, the function of which is not fully characterized. We tested the effects of the expression of the human c-Ha-ras-1 oncogene, derived from the EJ/T4 bladder carcinoma cell line, on the ability of the Chinese hamster V79 cells to conduct gap junctional communication. The junctional competence was studied by two different methods, the scrape-loading/dye transfer technique and the metabolic cooperation assay. The results indicate a strong correlation between the expression of p21 ras protein and the inhibition of gap junctional function. Assuming that reversible inhibition of intercellular communication plays a role during tumor

ABSTRACT: (U) Our present understanding of the
carcinogenic process, involving complex interactions of
genetic, developmental, sex, dietary and environmental
factors during the multistage initiation/promotion/
progression process of carcinogenesis, would lead us to
reject simplistic non-biologically based risk assessment
models. This understanding, plus recent results of the
National Toxicology Bioassay program and of the studies
of short-term tests for genotoxicity, has challenged the
primary paradigm of 'carcinogens as mutagens' which
governs our current risk assessment models. The concepts
of the stem cell theory of cancer, of oncogenes/tumor
suppressor genes, of gap junctional intercellular
communication, and of mutagenic and epi-genetic
mechanisms must be integrated into a biologically-based
model of the multistage nature of carcinogenesis. Current
understanding of the complex interactions during this
process prevents us from believing that a simple and
accurate, biologically-based risk assessment model will
be developed soon.

UNCLASSIFIED REPORT

ABSTRACT: (U) Our primary aim has been to study the electrophysiology of suprachiasmatic nucleus (SCN) neurons, with a focus on the interplay between intrinsic electrophysiological properties, amino-acid-mediated synaptic transmission, and neuromodulation. We have continued to study the role of excitatory and inhibitory amino acids (i.e., glutamate and GABA) in fast synaptic transmission in the SCN. Our work has provided strong evidence that these transmitters mediate all, or nearly all, of the fast synaptic potentials in virtually all SCN neurons. Preliminary experiments, however, suggest that a circadian rhythm of electrical activity persists after post-synaptic pharmacological blockade of these transmitter systems. Intracellular and whole-cell patch-clamp studies are being undertaken on intrinsic membrane properties, which we have found to be heterogeneous across the SCN. Particularly interesting is our recent observation that synchronous bursts of action potentials can occur in the SCN after chemical synapses have been blocked with low-calcium solutions and amino-acid-transmitter antagonists. Finally, we have continued several lines of experimentation partially supported by this grant on the suprachiasmatic and paraventricular nuclei and the preoptic area of the hypothalamus, thus allowing

AD-A247 313

AD-A247 313

UNCLASSIFIED

PAGE 28

T85004

a direct comparison between the SCN and other major regulatory areas of the hypothalamus. Our experiments continue to be aimed at providing a rigorous understanding of how transmitters and neuromodulators interact with intrinsic membrane properties to regulate the electrical activity of neurons in the SCN and other areas of the hypothalamus.

UNCLASSIFIED REPORT

ABSTRACT: (U) Highly excited vibrational levels of ground state iodine, and all levels of the metastable state, are involved in processes leading to the dissociation of I₂ in the chemical oxygen iodine laser (COIL). Populations in these vibrationally and vibronically excited levels can be sensitively monitored by exciting laser induced fluorescence (LIF) from the valance to ion-pair transitions. However, accurate spectroscopic constants are required for the extraction of population distributions from spectral intensity data. Constants for the systems were obtained from rotationally resolved spectra for jet cooled, metastable I₂. Studies of matrix isolated I₂ and IBr were undertaken in order to examine their electronic relaxation dynamics in simple cryogenic solids, and to determine the A and A' state radiative decay rates. Large matrix shifts were observed, caused by solvation of the excited state dipole. It is probable that an optically pumped laser, operating on the D'-A' transition of Ar matrix isolated I₂, could be constructed.

ABSTRACT: (U) The binding of the ADP unlimited ribosyl transferase protein and its polypeptide components, obtained by digestion with plasmin, to histone-Sepharose 4B matrices was determined by a centrifugation technique. Both the intact enzyme protein and the 29 kDa terminal polypeptide bound to histone affinity matrices in a strictly DNA-dependent manner. Whereas the nature of covalently matrix-bound histones had no apparent specificity towards the enzyme protein or its polypeptide components, among the polypeptides only the 29 kDa terminal basic polypeptide associated with the histone affinity matrices in a DNA unlimited dependent manner. The binding properties of spermine-, polylysine- and polyarginine- Sepharose 4B affinity matrices were also determined. The spermine matrix exhibited similarities to the histone affinity matrix, except binding was considerably weaker, whereas affinity matrices of synthetic polyamino acids showed individual variations but did not replace histones as affinity ligands. The catalytic significance of histone-enzyme associations was tested by determining the effects of the polypeptide components on the enzymatic ADP-ribosyl transferase reaction in the presence of a synthetic octadeoxyribonucleotide duplex as coenzyme.

ABSTRACT: (U) The Transient Internal Probe (TIP)
diagnostic is a novel method for probing the interior of
hot magnetic fusion plasmas that are inaccessible with
ordinary stationary probes, by limiting the time that the
probe is in the plasma, and by encasing the probe in a
diamond cladding. In the TIP scheme, a probe is fired
through a hot plasma at velocities in excess of 2.5 km/s,
and makes direct, local measurements of the internal
magnetic field structure. These measurements are relayed
to the laboratory optical detection system, using an
incident laser that is retroreflected through a Faraday
rotator crystal payload that acts as a magneto-optic
sensor. The individual tasks associated with the TIP
development, construction a two-stage light gas gun,
optical detection system and probe projectile, are
currently being completed. Integration of these tasks is
currently underway. It is expected that the integrated
system will be functional in the first six months of 1992.
A diamond ablation study has also been performed to
measure the ablative effects of a hot plasma in contact

ABSTRACT: (U) The mapping closure for the one point pdf of an inert scalar in homogeneous turbulence is explained and developed. It is shown that the pdf's calculated from the closure are in excellent agreement with those obtained from direct numerical simulations. The closure is then extended to many reactive scalars. In a turbulent reactive flow, the fluid composition at a point changes with time due to three processes: convection, reaction, and molecular diffusion. In probability density function (pdf) methods (Pope, 1985, 1991) the first two of these processes are treated exactly, but the effects of molecular diffusion have to be modeled. These different models have different attributes, but they all share two fundamental shortcomings: none has a sound physical basis; and none yields satisfactory results for the basic test case of a decaying inert scalar field in isotropic turbulence.

UNCLASSIFIED REPORT

ABSTRACT: (U) A model of a microwave-induced plasma propulsion system has been developed in one dimension for a transverse electric mode (TE sub 10) of operation in a rectangular waveguide. Available experimental data are compared to the computational results for the case of a planar propagating plasma wave and, using a TE sub 10 mode-shape approximation, for a wave propagating in a waveguide. Temperature profiles, plasma propagation velocities, velocity profiles, and absorbed power histories are obtained for flow of helium from .5 to 1 atmosphere pressure and 500 to 3000 watts input power at a frequency of 2.45 GHz. The computational results show the observed jumping of the plasma towards the microwave source. Peak plasma temperatures range from 8000 to 9000 K over the input power range. For an input power of 1081.7 W the calculated percentage of power absorbed in approximately 70 percent for the planar case and 40 percent for the waveguide case. Comparisons with experimental data indicate other mechanisms (not involving transient processes), most likely associated with the nonequilibrium behavior of the plasma, are responsible for the disagreement between the model results and the observed plasma propagation velocities.

UNCLASSIFIED REPORT

ABSTRACT: (U) Extensive experimental studies of small molecules as potential 'hosts' for short wavelength ($\lambda < 200$ nm) energy-storage lasers have been conducted. Laser spectroscopy of the rare gas dimers and Group IIB dimers have yielded structural constants for a significant number of previously unobserved states. Also, Fano 'windows' have been observed in Ne₂ in the energy region lying between $v(+) = 0$ and $v(+) = 3$ of the Ne₂(+) ground state X sq. Epsilon. Bound free emission studies of Cd₂ and Zn₂ have been carried out and the structural constants for the (1) Epsilon upper states have been determined. The growth of GaAs and GaN by photo-assisted MOCVD has also been demonstrated. Gallium arsenide has been grown epitaxially at temperatures as low as 450 C by illuminating the surface with ArF (193nm) radiation. Also, polycrystalline GaN (preferentially oriented (100)) has been grown on GaAs and sapphire at temperatures as low as 700 C and at growth rates exceeding 2 microns/hour.

DESCRIPTORS: (U) . CONSTANTS, DIMERS, EMISSION, ENERGY, ENERGY STORAGE, EXPERIMENTAL DATA, GALLIUM ARSENIDES, GROWTH(GENERAL), LASERS, MOLECULES, RARE GASES, RATES, REGIONS, SAPPHIRE, SHORT WAVELENGTHS, SOURCES, SPECTROSCOPY, STRUCTURAL PROPERTIES, TEMPERATURE.

UNCLASSIFIED REPORT

ABSTRACT: (U) Work for the grant's second year progressed in four projects. The first, a report of distorted space processing in flickering fields, concerns empirical work completed. The second project extended this work to high-speed flicker, at 480 and 980 Hz. No evidence was found that these high flicker rates have any advantages over slower rates, though some technical issues were resolved. The third project examined reading rates on CRT screens at 80 and 500 Hz. The faster rate resulted in reading that was on average 0.6 msec faster, a difference that is neither statistically reliable nor of practical consequence. Technical problems in that study were addressed in the fourth study, using more subjects and a larger and more difficult sample of reading material, with eye movement monitoring and an automatized screen refresh procedure. Initial results showed a small advantage in reading speed at the higher frequency for 4 to 6 subjects, and an overall advantage of 5 words/min at 500 Hz. Data collection is continuing in this project.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report describes recent results of studies designed to investigate the metabolic effects of perfluoro-carboxylic acids on liver carbohydrate and high-energy phosphorous metabolism. Carbon-13 nuclear magnetic resonance (NMR) spectroscopy was used in conjunction with 13 C isotope labeling to monitor the dynamic conversion of glucose to glycogen in rat liver in vivo. The results show that perfluoro-decanoic acid (PFDA) causes a marked inhibition in hepatic glycogen synthesis in rats at 3 days post treatment (n=5) and complete inhibition at 5 days post dose (n=5). Hepatic glucose and blood glucose levels are also slightly elevated within the first 15 min. following a glucose load in PFDA rats versus controls (p<0.05). Preliminary data reveal that glycogen synthesis from alanine via gluconeogenesis is functional in PFDA-treated rats. This suggests that the inhibition in glycogenesis from glucose may involve the transport of glucose into hepatocytes and/or its phosphorylation by glucokinase. Further studies are in progress which investigate this hypothesis. In studies of the high-energy phosphorous metabolism in PFDA-treated rats, P31 NMR reveals normal ATP levels and an anomalous signal in the phosphomonoester region of the liver spectrum. The source of this phosphorous metabolite has not yet been identified and is the focus of ongoing research efforts.

UNCLASSIFIED REPORT

ABSTRACT: (U) The dynamics of ion-molecule collision processes have been explored in flowing afterglow-drift and single collision instruments using laser-induced fluorescence and Doppler resolved laser probing. The velocity distributions of Ba⁺ drifted in both helium and argon buffer gases have been determined and compared with theoretical predictions. Ion mobilities and parallel and perpendicular temperatures have been measured as a function of field strength; in addition, the first experimental determination of skewness parameters has been made for Ba⁺ in argon. Small but definitive differences in the mobility and temperature of CO⁺ in helium have been observed for different rotational states of CO⁺; moreover, in contrast to results for atomic systems, the parallel and perpendicular temperatures have been determined to be nearly identical. Preliminary studies of the rotational alignment of the 1,3,5-trifluorobenzene cation have been carried out; in some spectral regions, substantial polarized laser-induced fluorescence was observed. Product vibrational excitation for the proton transfer reaction D⁺ + HF was measured as a function of enhanced collision energy; in contrast to results for neutral systems, the fraction of total energy entering vibration was found to increase slightly as the reagent collision energy is increased. Rotationally state-resolved product state distributions have been obtained

ABSTRACT: (U) This report summarizes the work performed during the first year of a two year program aimed at demonstrating the feasibility of constructing a 4-dimensional neural network based on the unique properties of spectral hole burning (SHB) materials. The work is progressing as originally planned with the basic optical system nearly complete and tested. The necessary SHB materials have been synthesized and excellent quality holograms have been recorded and retrieved. Both wavelength and angle multiplexing have been demonstrated with no apparent crosstalk. The system design has been precisely defined and all key components have been selected. A discussion is presented describing a set of initial tests which are aimed at verifying the basic operational capabilities of the system. The next phase of complete system integration and testing will soon begin.

ABSTRACT: (U) Purified adenosine diphosphoribose transferase protein binds to RNA-DNA hybrid templates of reverse transcriptase at the DNA primer site and inhibits RT activity of HIV and MMU RTs. This action is prevented by auto-poly-ADP-riboseylation of the transferase but is reinduced by inhibitory ligands of the enzyme. ADPRT is a highly abundant non-histone nuclear protein of higher eukaryotes and there is convincing evidence that the poly(ADP-ribose) synthesizing function of this protein represents only a few percent of its molecular activity in intact cells. This is in agreement with the magnitude of the DNA-independent rates of oligo (ADP-ribose) synthesis which can be readily determined even in the 58 kDa polypeptide fragment of ADPRT that has no DNA recognition sites.

 1990.

ABSTRACT: (U) Adenosine diphosphoribosyl transferase is
 a DNA binding eucaryotic nuclear protein that catalyses
 the polymerization of ADP-ribose, which is derived from
 (oxidized nicotinamide adenine nucleotide) NAD⁺. These
 homopolymers are covalently bound to ADPRT and certain
 other nuclear proteins such as histones, topoisomerases,
 RNA and DNA polymerases. This post-translational
 modification process has been implicated in various
 biological processes including repair and replication of
 DNA (1-3). DNA is absolutely required for the enzymatic
 activity of ADPRT. In the absence of NAD⁺, the enzyme can
 bind to DNA. An understanding of the DNA-binding
 mechanisms of ADPRT is considered critical for the
 elucidation of its cellular role. We showed previously
 that ADPRT binds to relaxed closed circular SV40 DNA and
 induces superhelicity, as assayed employing the nicking
 and closing activity of topoisomerase I. We have also
 demonstrated that ADPRT binds to a 209 bp EcoRI-PstI
 fragment of SV40 DNA. ADPRT was shown to selectively bind
 the internal regions of the 209 bp EcoRI-PstI SV40 DNA
 fragment but not the internal regions of other linear
 DNAs tested.

UNCLASSIFIED REPORT

ABSTRACT: (U) This is the final technical report on a project designed to apply the experimental techniques of modern surface science to address issues loosely related to the combustion of boron particles. Boron particles have potential application as a fuel. Our experiments focused on the reaction of O₂ with the (111) surface of Beta-rhombohedral boron to produce B₂O₃ and the subsequent reactions involved in desorbing B₂O₃ from the boron surface. We find that the reactivity with O₂ is low throughout the temperature range of 300-1300 K. We find that the net uptake of O by the surface is at a maximum in the temperature range of 800-1100 K but that at most only submonolayers of B₂O₃ are formed. When B₂O₃ is directly deposited on the surface, it reacts with the substrate in the temperature range of 1100 to 1300 K to produce B₂O₂. In separate experiments, we have used scanning tunneling microscopy to obtain atomically resolved images of the LaB₆ (100) surface.

ABSTRACT: (U) Using specific inhibitors, a plant cell/
microbe cocultivation assay was employed to investigate
biochemical mechanisms of plant activation. The
biological endpoints of mutation induction, inhibition of
mutagenicity and viability of the plant-activating system
as well as viability of the microbiological indicator
were simultaneously assayed from the same reaction tube.
We investigated six inhibitors of monooxygenases and
oxidases (diethyldithiocarbamate, methimazole, metyrapone,
(+)-catechin, 7,8-benzoflavone and potassium cyanide).
The activation of 2-aminofluorene by TX1 cells was
mediated by an enzyme system(s) that was inhibited by μ M
amounts of diethyldithiocarbamate or 7,8-benzoflavone. (+)
-Catechin (at low concentrations) or methimazole enhanced
the activation of 2-aminofluorene while higher
concentrations of (+)-catechin were inhibitory. These
data indicate that a significant pathway of the plant
activation of 2-aminofluorene is via a cytochrome P-448-
type N-hydroxylase. The presence of a FAD-dependent
monooxygenase was not detected.

ABSTRACT: (U) The propensity of chlordecone (CD) to potentiate the hepatotoxic and lethal effects of CCl₄ is well established. Mirex (M), a close structural analogue of CD, or phenobarbital (PB), both powerful inducers of hepatic microsomal drug metabolizing enzymes, are much weaker potentiators of CCl₄ toxicity. Considerable evidence has accumulated to suggest that this increase in CCl₄ toxicity caused by CD is due to the failure of the hepatocellular regeneration, tissue repair and hepatobular restoration mechanisms. This interaction occurs at concentrations of CD and CCl₄ that are individually non-toxic and do not interfere with hepatocellular division. To test this unique interaction at cellular level, we employed a rapidly dividing Reuber hepatoma cell line in vitro. Cells were pretreated with a non-toxic dose of either CD, M or PB and exposed to a single addition of CCl₄ in the concentration range 5 to 40 mM 16 days later. The results indicate that CD + CCl₄ combination specifically arrested hepatocellular division. The inhibition of cell division occurred at individually non-toxic concentrations of CD and CCl₄. M + CCl₄, or PB + CCl₄ failed to manifest similar effects. At higher concentrations, these combinations caused cellular toxicity, resulting in cell death. Suppression of cell

division might play an important role in the progression of chemical-induced toxicities in the liver. This unique observation opens up new avenues to investigate biochemical molecular mechanisms underlying the interference with hepatocellular division.

UNCLASSIFIED REPORT

ABSTRACT: (U) The overall aim of this research is to investigate the neural circuit mechanisms of attentional and discriminative processing of somatosensory stimuli which are cues for limb movement. These issues are being addressed mainly through use of multi-single neuron recording techniques, which we have recently developed. In the past granting period this approach has been used to record from ensembles of single neurons through microwire electrode arrays chronically implanted in the forepaw/forelimb areas of the somatosensory (SI) and motor (MI) cortices in awake behaving rats. These animals are trained to place their forepaw on a bar and move it up or down immediately upon detecting a vibratory stimulus imposed on the bar. Initially, only neurons in the SI responded to the sensory cue. After the rat learned to perform to criterion in the task, however, neurons in the MI cortex also responded at relatively short latency to the sensory cue. This suggests that transmission through a trans-cortical sensorimotor loop can be enhanced through training. Additional progress has been made on several other projects which provide necessary background information for this investigation. Selective attention, discrimination, motor response, somatosensory system, cerebral cortex circuit function

ABSTRACT: (U) Ecologically realistic laboratory and
field simulated ecosystems (microcosms and mesocosms) are
playing increasing roles in fate and effect testing of
chemicals and mixtures. Controlled ecosystems allow
evaluation of toxicant effects on collective and emergent
ecosystem properties. Information is needed to evaluate
the validity of test system responses, interpretability
of results, and cost effectiveness of simulated ecosystem
tests. We developed replicate microcosms using periphyton
on polyurethane artificial substrates. Source communities
were obtained from two ecosystems-a reservoir in Kentucky
and a softwater pond in Virginia-and tested for effects
of continuous inputs of phenol (up to 30 mg/L) over 21
days. System responses measured included several biomass
estimators, net oxygen production, and protozoan species
richness. Communities were generally insensitive to
phenol input. Primary production in microcosms from both
ecosystems was inhibited at phenol concentrations >10 mg/
L and chlorophyll a concentrations were also depressed.
Other biomass estimators (protein, hexosamine) were not
affected or were stimulated at lower (equal or less than
10 mg/L) phenol concentrations. Protozoan species numbers

ABSTRACT: (U) Microbial colonization of artificial
substrates introduced into aquatic ecosystems is affected
by the relative levels of nutrients and toxicants. The
productivity of microbial biota integrates several
factors affecting organism survival and is expressed in
relative rates of propagule production and colonization.
Colonized artificial substrate species sources can be
used in the laboratory to measure nutrient and toxicant
effects. Studies have shown that microbial colonization
is at least as sensitive a technique as long-term single-
species testing and has allowed controlled measurement of
complex community responses to disturbance. It is
possible to model the nonlinear colonization process and
to compare colonization rates, equilibrium species
numbers, and biomass production in test systems. The
authors found adverse effects on species dispersal in
static test systems for cadmium and copper at
concentrations of < 1 ug Cd/L and 18 ug Cu/L, although
low levels of copper enhanced the species numbers. In
microcosm systems receiving continuous toxic input, we
found adverse effects of chlorine on species dispersal at
2 ug/L; however, net production was elevated at

AD-A247 220

AD-A247 220

UNCLASSIFIED

PAGE 44

T85004

concentrations up to 100 ug/L. In tests with the
herbicide atrazine, the number of species and the net
production were stimulated at low levels (3 to 30 ug/L).
Stimulation of the species number and production may be a
result of effects on control mechanisms and not the
result of a subsidy to the community. The study of
natural community dynamics in evaluating the effects of
toxic materials provides evidence of effects on the
emergent properties of systems. Hazard evaluation,
Microbial colonization, Microbial communities, Artificial
substrates, Microcosms, Toxicity, Microbial production,
Protozoa, Heavy metals.

UNCLASSIFIED REPORT

ABSTRACT: (U) Our object was to provide chemists with theoretical procedures that could serve as practical adjuncts to experiment in studies of chemical problems, in particular studies of reactions and reaction mechanisms. We succeeded for the elements which have sp valence shells and main group elements where d AOs serve only as polarization functions, but attempts to extend this approach to elements with spd valence shells all failed. We had no experience of ab initio programming so we wrote a general program from scratch. Full scale parametrization for the organic elements (CHON) is now in progress. Computer programs were written for treating biradicals in procedures for correlation between the unpaired electrons. Proportionality factors were found by matching the singlet-triplet separations in carbene and singlet-triplet separations were then calculated for large numbers of other carbenes. AM1 parameters were optimized for aluminum, sulfur, germanium, tin, and mercury. We developed a new version of the DEWARPI procedure in which geometries are found by minimizing the total energy. We developed a new version of the AMPAC program at QCPE (AMPAC2.1) for a very effective method for finding transition states. AM1 Parameters, AM1 Calculations, Germanium, Aluminum, DEWARPI, PPM3 Method, Tin, Ab Initio, Molecular Orbital.

ABSTRACT: (U) Impact of a toxic municipal sewage
effluent containing textile dyes was evaluated using
standard acute and chronic single-species tests and a
microcosm test using indigenous microbiota from the
receiving stream. Estimated effect levels were compared
with the calculated in-stream waste concentration and
measured impacts on stream microbiota and macrobenthos.
Acute tests examined effluent effects on *Daphnia pulex*,
and short-term chronic effluent dilution tests were
conducted using *Ceriodaphnia dubia* and larval *Pimephales*
promelas. Effluent concentrations of 70% were acutely
toxic in median effective concentrations) to *D. pulex*.
Estimates of the no-observable-effect concentration (NOEC)
were 10 and 7.5% for *C. dubia* and *P. promelas*,
respectively. Responses in the microcosm systems were
nonlinear and showed significant subsidy of both
structure and function at concentrations of 30% and
toxicity at concentrations >30%. Tests of receiving
stream water below the effluent outfall showed a slight
depression of reproduction in *C. dubia* and recovery to

upstream levels for water sampled from farther downstream.
Surveys of in-stream microbiota and macrobenthos
confirmed adverse impacts below the discharge and
indicated recovery 11 km downstream. Microcosm tests were
generally less sensitive than single-species tests in
detecting toxicity of the effluent. The sensitivity of
the tests may have been improved by improving the test
conditions, including continuous replacement of effluent,
as was done in larval *P. promelas* tests. To be effective
in predicting in-stream effects, the design of intensive
toxicity surveys should make every effort to mimic local
conditions. *Ceriodaphnia*, *Pimephales promelas*, Microcosm,
Artificial substrates, Sewage effluent, Effluent toxicity.

UNCLASSIFIED REPORT

ABSTRACT: (U) Work focussed on describing the solar activity cycle's clock as a torsional oscillator, and describing the origin of the 5 minute oscillations, which are used as a seismic probe. It has been discovered that the sun's rotation does not vary near the base of the convection zone but may vary deeper down. The full equations for the torsional oscillator have been developed and have been solved for certain situations. It has been shown that the 5 minute oscillations are driven by granular size explosive events. In observational work, the observing set-up has been designed to capture the whole solar disk. Data is now able to be collected in a production mode. Data reduction programs also are in full operation. The basic behavior of 5 minute oscillations has been clearly seen. A search is underway for the global organization of convection to determine if giant cells exist.

ABSTRACT: (U) The program was to explore the use of light to manipulate atoms and other particles, particularly the cooling and trapping of atoms, the manipulation of biological molecules, and the creations of new devices based on these techniques.

ABSTRACT: (U) Five tasks were initiated to study the aerodynamic interference between stores and aircraft. Both viscous and inviscid calculations were made. Steady state interference calculations matched well with experimental results and with other computational results. Unsteady time-accurate inviscid results showed the feasibility of using the Chimera scheme to simulate store separation. Free-fall calculations were made, demonstrating the ability to compute the new position of the store from the aerodynamic forces and moments on the store after its release from the aircraft. ABSTRACT: (U) Significant progress was made in a number of aspects of nonlinear and stochastic systems. An important problem in the adaptive control of a finite state Markov chain was solved, and significant progress was made along more general directions. A controlled switching diffusion model was developed to study the hierarchical control of flexible manufacturing systems and significant results were obtained. In the area of deterministic nonlinear systems the work continued on nonlinear observers and linearizable dynamics. Finally, some important problems in the area of discrete event systems were solved.

ABSTRACT: (U) The goal of our research was to bridge the gap between modern ideas from dynamical systems and chaos and more traditional approaches to turbulence. In order to reach this objective we conducted theoretical and computational work on two systems: (1) a perturbed-Kelvin cat eyes flow, and (2) prototype solutions of the Navier-Stokes equations near solid walls. The main results obtained are two-fold: (a) we have been able to produce flows capable of producing complex distributions of vorticity, and (b) we have been able to construct flowfields, based on solutions of the Navier-Stokes equations, which are capable of displaying both Eulerian and Lagrangian turbulence. These results exemplify typical mechanisms of mixing enhancement in transitional flows. Fluid mechanics, Chaos, Mixing, Turbulence.

ABSTRACT: (U) The problem of locking, which arises in the approximation of parameters dependent problems has been extensively investigated. A general theoretical framework to analyze this phenomenon has been developed, and the locking and robustness of different finite element schemes for various problems has been characterized. Work on the p and h-p versions of the finite element method has continued. Progress here includes optimal approximation results for the p version of the boundary element method in three dimensions, an analysis of a p version mixed method for quasilinear problems, and investigation of quadrature schemes and related errors. Additional work has been conducted on singularities of solutions for the three dimensional elasticity and hydro dynamics equations in domains with edges and vertices, on the numerical evaluation of singular surface integrals in the boundary element method, and the calculation of optimal shear correction factors for plate models.

UNCLASSIFIED REPORT

ABSTRACT: (U) This investigation focussed on the development of instrumentation for the study of atomization and two-phase turbulent flows including sprays in reacting turbulent flow. Four methods were investigated: the phase Doppler method, ratimetric light scatter detection, Lagrangian frame particle dynamics analyzer, and scattered light heterodyne interferometry. For the phase Doppler technique, the physics of the dual beam light scattering phenomena, the effects of particle morphology on the light scattering, the effects of the nonuniform illumination of the particle, and the consequences of the random particle trajectories were investigated. Sampling statistics were also considered. The ratimetric light scatter detection method was used to size irregular shaped and inhomogeneous particles using the scattered light intensity in the near forward direction. The uncertainty due to the particle trajectory through the beams was removed using an optical deconvolution approach. A Lagrangian method for tracking individual particles was investigated. A rapidly swept light sheet produced a series of images of an individual particle on an array detector, from which the particles' position and velocity were obtained. This method is feasible given sufficient laser power and/or a large enough particle. Scattered light heterodyne interferometry posed significant limitations which

UNCLASSIFIED REPORT

ABSTRACT: (U) Our research concerned the manners by which the monaural and binaural auditory systems deal with progress was made consistent with the objectives process information in complex sounds. SubSten outlined in the original proposal in three areas: (1) New electronic equipment, including a NeXT computer was purchased, installed and interfaced with the existing laboratory. Software was developed for generating the necessary complex digital stimuli and for running behavioral experiments utilizing those stimuli. (2) Monaural experiments showed that the CMR is not obtained successively and is reduced or non-existent when the flanking bands are pulsed rather than presented continuously. Binaural investigations revealed that the detectability of a tonal target in a masking level difference paradigm could be degraded by the presence of a spectrally remote interfering tone. (3) In collaboration with Dr. Richard Stem, theoretical efforts included the explication and evaluation of a weighted-image model of binaural hearing, attempts to extend the Stern-Coibum position-variable model to account for many crucial lateralization and localization data gathered over the past 50 years and the continuation of efforts to incorporate into a general model notions that lateralization and localization of spectrally-rich stimuli depends upon the patterns of neural activity

UNCLASSIFIED REPORT

ABSTRACT: (U) In 1991 we continued our investigations on the involvement of membrane lipid metabolism in the presynaptic processes related to the evoked release of the neurotransmitter glutamate. In particular, we observed that the phospholipase A2-dependent release of arachidonic acid from mossy fiber membrane phospholipids may modulate transmitter secretion through interactions with protein kinase C (PKC). The activation of PKC may explain the previously observed facilitation of depolarization-evoked Ca^{2+} accumulation and glutamate release induced by exogenous arachidonate. These facilitatory effects may be related to the induction of long-term synaptic potentiation, which is an accepted correlate of learning and memory. In addition, we obtained evidence that presynaptic receptor activation stimulates the synthesis of arachidonate-derived prostaglandins. Thus, the metabolism of arachidonic acid may play a central role in presynaptic plasticity.

UNCLASSIFIED REPORT

ABSTRACT: (U) Three lines of study were outlined in the previous report: (1) to test the efficacy of the catecholamine precursor L-Tyrosine in reducing pilot performance deficits caused by sleep deprivation, 2) to assess the role of endogenous melatonin on various performance and behavioral indices through photic modulation of nocturnal melatonin secretion and 3) to examine the effects on the same performance and behavioral variables of exogenous melatonin administered during the day. The data have been collected for all three studies, involving 14, 24, and 21 human volunteers respectively, and analysis is in progress. Preliminary analysis of the results are consistent with the hypotheses upon which the studies were predicated and provide a basis for a more fruitful continuation and elaboration of this investigation. L-Tyrosine, Melatonin, Stress, Performance, Pilots, Light Sleep Deprivation, Human.

UNCLASSIFIED REPORT

ABSTRACT: (U) Normal and axial force indicial responses for a 2-D NACA 0015 airfoil undergoing small step changes in angle of attack have been measured in a tow tank. The airfoil was pitched about the quarter chord and the Reynolds number, as 95,000. First order and it second order tests were conducted. In the first order tests, the angle of attack prior to the step onset was held constant. In the second order study, the airfoil and was ramped up at constant rate to the onset angle. Step onset angles in the range $0 < \alpha < 80$ deg were considered. The step responses have been integrated numerically to compute the loading during a ramp-up motion. The integrated results are compared with baseline load data taken with the same airfoil. Nonlinear Aerodynamics, Indicial Responses.

Availability: Pub. in Basic Plasma Processes on the Sun, p507-507 1990. Available only to DTIC users. No copies furnished by NTIS.

ABSTRACT: (U) VLA observations at 20 cm wavelength specify the brightness temperature and magnetic structure of plasma constrained within coronal loops in solar active regions. Comparisons with simultaneous SMM observations at soft X-ray wavelengths lead to measurements of physical parameters like electron temperature, electron density and magnetic field strength. Such comparisons also indicate coronal loops can be detected at either radio or X-ray wavelengths while remaining invisible in the other spectral domain, and that the dominant radiation mechanisms can be thermal bremsstrahlung or thermal gyroresonance radiation. VLA observations at the longer 90 cm wavelength reveal the thermal emission of a hot transition sheath enveloping a cooler, underlying H-alpha filament seen in absorption. The 20 cm VLA observations indicate that the precursor, impulsive and postflare components of solar flares originate in spatially separated and resolved sources. Sun- corona, Sun - radio radiation.

UNCLASSIFIED REPORT

ABSTRACT: (U) An Imaging Doppler Interferometer (IDI) radar was operated to analyze the characteristics of radar scattering in terms of a number of discrete scattering points, also referred to as multiple scattering centers, IDI/MS for short. For each of these points the three-dimensional location, radial velocity, and amplitude and phase are determined, similar to the output of meteor radars. The conventional Groves' meteor wind radar analysis was applied to the scattering points to produce the mean apparent motions over the height range from 70 to 110 km. The mean apparent motion of the scattering centers is the quantity that would correspond to the neutral atmosphere wind or bulk motion if the scattering points are physical entities (such as turbulent eddies) whose motions are determined solely by advection. This is the quantity which is treated as the 'wind' in the analysis and which should be compared to the wind measurements as deduced from the other methods employed during this campaign. Extreme care must be used in interpreting the velocities measured by partial reflection radars as winds.

DESCRIPTORS: (U) *RADAR REFLECTIONS. *GRAVITY WAVES.

UNCLASSIFIED REPORT

ABSTRACT: (U) Two types of texture segregation occurs. Preattentive texture segregation has been shown to occur as a result of differences in the outputs of Gabor filters that operate on intensity values and as a result of the grouping of discrete elements through edge alignment and lightness similarity. Texture segregation based on these properties occurs preattentively. A second type of texture segregation appears to depend on attention. Texture segregation appears to depend on interpretation of projected shapes appears to require a focussing of attention. Attention acts to trigger texture segregation. Attention is required to see a 2D figure as three-dimensional. The 3D interpretation is propagated in parallel or rapidly to the other figures in the pattern and texture segregation occurs in terms of the differences in the perceived orientations off the 3D figures. A necessary condition for texture segregation is the rapid processing of stimulus differences. Texture segregation does not occur if discrimination of the relevant stimulus differences requires sequential attentional processing. Vision, Texture segregation.

UNCLASSIFIED REPORT

ABSTRACT: (U) We have completed the assessment of the diurnal variation in serotonergic activity in the SCN and its temporal relationship to wheel-running behavior under lightentrained (LD 14:10) and free-running (DD) conditions. First, under LD there was a marked diurnal rhythm in serotonergic activity with peak levels occurring at lightoff during the animals' initial bout of wheel-running activity. Thereafter, serotonergic activity decreased to daytime levels by the next morning, despite robust bouts of nocturnal wheel running behavior. Also, daytime periods of activity exhibited by some individuals was not associated with increased serotonergic activity. From these results, it is hypothesized that serotonin in the SCN does not acutely trigger motor activity. Instead it appears that serotonin is involved in coordinating light-entrained activity rhythms with the LD cycle, which is consistent with the findings of other researches using lesions or pharmacological approaches. Our second original finding is that the diurnal rhythm in serotonergic activity is lost, or greatly diminished, in free-running hamsters held under DD for 3 wks. Thus, the rhythm in serotonergic activity seen under LD probably is not circadian in nature, but is passively driven by an external influence, i.e. the light-dark cycle.

ABSTRACT: (U) The Reduced Navier-Stokes (RNS)
formulation for viscous-inviscid interacting flows with
significant upstream or 'elliptic' effects has been
applied for transient flows in inlets and steady two and
three dimensional flows over cone-cylinder flare,
afterbody and channel configurations. The solution
technique allows for shock-boundary layer interaction and
for regions of axial and secondary flow recirculation. It
has been demonstrated that for laminar flows there exists
a critical Reynolds number above which the solution
exhibits a breakdown. This behavior, which occurs in the
region of recirculation and can be correlated with the
transition location, is grid dependent and can be missed
with insufficiently refined grids or when artificial
viscosity is introduced. The pressure-split RNS procedure
is a special form of flux-vector splitting that has very
favorable properties for sharp shock-shock and shock-
boundary layer interaction. A sparse matrix direct solver
procedure has been applied for both two dimensional
transient flows, and for three dimensional steady flows.
A domain decomposition multigrid procedure has further

ABSTRACT: (U) A small group of researchers met recently to review the new and rapidly growing field of many-atom potential for solids. The workshop was held on September 25-27, 1991, in Ann Arbor, MI, and was commissioned by the Air Force Office of Scientific Research. Some classes of materials are being well treated by many-atom potentials, while others are just now being considered. Combinations of materials including more than one type of bond seem clearly beyond our present capabilities. The systematics of many-atom potential development are in their infancy, and progress appears to be rapid.

UNCLASSIFIED REPORT

ABSTRACT: (U) A state of the art, fully functional, multi-scale and multi-channel segmentation tool has been developed. It is based on the recently developed computational theory of the 2-normal segmentations. A fast multi-scale pyramidal algorithm has been designed and applied to the theoretical variational segmentation model of Mumford-Shah. This algorithm has a multi-channel capability, as well as a much more general class of solutions. Namely, a piecewise polynomial segmentation is natural to the pyramidal multi-channel framework. The piecewise affine segmentation has been implemented and tested. Application specific channels include: gray scale information, two-dimensional wavelet channels for texture discrimination, and multi-scale singular feature channels. The accuracy of the pyramidal segmentation algorithm has been experimentally compared to the accuracy of two other modern segmentation algorithms. The performance of the pyramidal algorithm has shown an average four-fold reduction in error measurements. Computational experiments with reconnaissance photography, multi-sensor satellite imagery, medical CT and MRI multi-band data have shown a great practical potential of this novel technique. Preliminary experimentation in clutter removal via multi-channel segmentation points to a totally new class of feature preserving decluttering algorithms.

ABSTRACT: (U) (1) Evidence that intersubject differences in the ability to process MD shape are not predicted by the ability to process luminance-defined (LD) shape, that motion is processed in a hierarchical manner. (A) Reducing presentation duration or dot lifetime from 1.0 to 0.1 sec progressively reduced the visibility of a MD bar, but did not reduce orientation discrimination for the bar when visibility was held constant. (B) Detection and/or recognition of MD letters can be degraded by removal of brain tissue underlying prestriate cortex without affecting contrast sensitivity. Snellen acuity, low contrast acuity or sensitivity to motion. (2) Human subjects have excellent ability to process camouflaged MD shapes. (3) The human visual pathway is directly sensitive to the time to collision with an approaching object. We have modelled this processing, and report a method for measuring intersubject differences in discrimination of time to contact. (4) By recording the magnetic field of the brain we have identified an audio-visual integration area in the brain. (5) We have developed a technique for measuring intersubject differences in susceptibility to glare, and are using it in prospective study of flying safety. Also, the test quantifies visual status in cataract patients. (6) Our motion-defined letter test is now freely available, and we are using it in a prospective study of helicopter

T85004

UNCLASSIFIED REPORT

ABSTRACT: (U) Poly(ADP-ribose) polymerase requires DNA for activity, and the catalytic activity of this enzyme is directly coordinated to the number of DNA strand breaks in DNA. Use of molecular techniques and the complete amino acid sequence of the enzyme, established during the past granting period, should allow us to learn considerably more about the mechanism and role of this enzyme in cells exposed to stressful environments. In AIM I, we proposed to extend our preliminary data on the insertion of full-length polymerase cDNA into various inducible and non-inducible expression vectors and retroviral vectors in both sense and antisense orientations. This would allow us to either inhibit (i.e. through antisense mRNA expression) or intensify the translation of polymerase in a variety of eukaryotic cells. A complementary approach was proposed in AIM II where various functional domains of the polymerase as well as site-directed mutants were to be constructed into inducible expression vectors to test whether selective inhibitor's can be favorably used in cells. Once it was verified that both the engineered mRNAs and appropriate peptides were expressed in in vivo procedures in AIM II we proposed to test for cytotoxicity and DNA repair potential and mutagenesis repair of the various reconstructed cells obtained in AIMS I AND II. poly(ADP-

ABSTRACT: (U) This project investigated the cellular, molecular and biochemical mechanisms that control the response of the rat adrenal gland to physiological stimulation. We found that the responsiveness of this tissue will change following specific treatments including chronic treatment of rats with insulin and acute depolarization of the cells with KCl. The alternation in adrenal reactivity appears to be directly correlated with the cellular concentrations of catecholamine neurotransmitters. This past year has been spent investigating the biochemical mechanisms that may be responsible for this change in bioreactivity. Since the most important biochemical mechanism controlling cellular function is protein phosphorylation, we focussed on this method of control. We have identified a novel protein kinase activity that phosphorylates both tyrosine hydroxylase and synapsin at a unique site. Most recent research has involved the phosphorylation of other structural proteins by this proline-directed protein kinase. In addition, we have examined the role protein kinase C in regulating the response of PC12 cells to a variety of growth factors in culture.

ABSTRACT: (U) The CNS Project combines several noninvasive methods for monitoring brain structure and function in a test battery. Phase One (1988-1991) focussed on neuroanatomical and neurophysiological correlates of behavioral ear advantages for two sets of complex sounds. Fifteen subjects neurologically normal according to conventional standards were tested with dichotic listening (2 measures), NM (2 measures), evoked potentials (2 measures), and qEEG (4 measures). One subject was also tested under similar conditions with PET. Results indicated: (1) Each individual had a distinct sidedness bias articulated in terms of a combination of anatomical and physiological variables, (2) These individual patterns cut across conventional categories such as gender and handedness, (3) In some of the subjects, these CNS profiles comprised internally consistent patterns of asymmetries linking subcortical physiology, cortical anatomy and cortical physiology. (4) In others, departures from such consistency signalled evidence of a variety of subtle neuropathologies, such as stuttering, mild learning disorder, central auditory dysfunction, or a history of hyperactivity and/or substance abuse. brain imaging, human neuroscience, brain asymmetries, evoked potentials, qEEG, MRI, PET.

ABSTRACT: (U) The solar cycle is a magneto-fluid-dynamical process whose intensity varies cyclically in a time of about eleven years. Its arrhythmas reveal it to be a chaotic process that has intermissions every few hundred years. Our aim in this project is to capture the essential physical mechanisms underlying this behavior and to describe it in a mathematically simple model. We have studied the mathematical form such models may take and seen the causes of intermittency. We have isolated the probable seat of the solar cycle in the shear layer recently detected by helioseismology just below the convection zone. We call this layer the solar tachyline because of certain analogies to the oceanic thermocline. Using the methods of bifurcation theory to describe the nonlinear dynamics of this layer, we have uncovered a spatio-temporal behavior like that of the butterfly diagram characterizing the sunspot cycle. And, finally, we have uncovered in the turbulence of the tachyline, a promising mechanism for the formation of sunspots that is linked to the processes of vortex formation in geophysical fluid dynamics. Sunspot Intermittency, Solar cycle, Tachyline, Dynamo Chaos.

UNCLASSIFIED REPORT

ABSTRACT: (U) Hydrazines (HZ) are toxic compounds which have numerous industrial applications including their use as missile propellants in advanced aircraft such as the F-16 and space vehicles. The extremely high toxicity of HZs and the recurrent accidental exposure due to routine storage, use, and disposal of these compounds have created a significant health hazard among aerospace and defense industry personnel. HZ exposure can result in lethal complications involving repeated seizures and eventual respiratory collapse. Acute HZ exposure produces repeated tonic-clonic seizures in animals and man due to the strong convulsant properties of these compounds. In order to develop effective therapies for HZ toxicity, it is important to determine the mechanisms by which HZs produce their neuronal excitatory effects. Initial studies in our laboratory of the electrophysiological effects of HZs have shown that HZ exposure induces spontaneous and evoked epileptiform activity in mammalian hippocampus, recorded in vitro. In cultured hippocampal neurons, we have found that HZs decrease the postburst afterhyperpolarization, a primary postsynaptic mechanism utilized by many types of neurons to terminate bursts, and maintain a check on hyperexcitability. As expected, this AHP reduction by HZs increases the rate of sustained repetitive firing in these neurons, and may be one mechanism contributing to HZ convulsant actions. The overall objective of this study is to describe and

pharmacologically characterize HZ-induced epileptiform actions in hippocampus, and to examine the effects of HZs on ion conductances in mammalian hippocampal neurons, in order to provide insight into the mechanisms of HZ toxicity which may underlie the excitatory and epileptogenic properties of these compounds.

ABSTRACT: (U) The purpose of the 1989 NATO ARW was to develop applications for and an improved understanding of the physics for high current emission and conduction observed in hollow cathode-hollow anode switches including the pseudospark and back-lighted thyratron (BLT). New applications include highly emissive cathodes for microwave devices, accelerators and free electron lasers, high power tubes, electron and ion-beams, microlithography, accelerators, and other plasma devices. Recent research has produced this new generation of gas-phase plasma switches that are characterized by very high current emission and conduction while operating in a glow mode. The cathode properties are especially remarkable - about 2 orders of magnitude larger emission than existing thermionic cathodes. Part of the meeting was devoted to understanding these properties, and exploiting applications of this cathode. These results deserve study in order to understand the underlying physical mechanisms, and to develop ideas and insight into future applications, and to foster coherent research in this area. This meeting was also motivated by the fact that there are many new applications of these devices under consideration. These include new n and electron beams for microelectronic technology, accelerators, other plasma loaded devices, plasma lenses for high energy physics, plasma

ABSTRACT: (U) Due to the basic nature of military operations, it is sometimes necessary for Air Force personnel to be exposed to toxic chemicals in their work environment, either as a protracted low-level exposure or as a high-level, acute exposure. The Draize rabbit eye test for acute irritation has come under severe criticism by the animal rights movement and has undergone legislative restrictions. Therefore, the tissue culture test being developed is likely to commercial as well as scientific benefit. Progress by Topical Testing during the past year has been on a number of technical fronts including the development of data collection software and a method for delivery of microquantities of toxic chemicals to individual nerve cells in tissue culture. The neuronal cultures are now viable and reproducible, and their response to a variety of chemical stimuli has been recorded. Corneal epithelial cultures have been viable for a number of months. A number of strategies have been explored to expand the corneal epithelial culture and thus make it a viable commercial system. In summary, Topical Testing has made substantial gains in the development of a commercial assay system, and next year will focus on testing the system's response to different classes of toxic chemicals. Bioassay, Environmental toxins, Detoxification, Tissue Culture.

ABSTRACT: (U) Glutathione conjugation reactions, which may detoxify xenobiotics through mercapturic acid formation, have been identified as an important bioactivation mechanism that may be responsible for the nephrotoxicity and nephrocarcinogenicity of certain halogenated hydrocarbons. Two types of toxic S conjugates have been identified: The glutathione S-transferase-catalyzed reaction of glutathione with 1,2-dihaloalkanes may lead to glutathione based sulfur mustards, which are direct-acting alkylating agents. The transferase-catalyzed reaction of glutathione with halogenated alkanes may yield S-(haloalkyl) or S-(haloalkyl) glutathione conjugates, which, after transport to the kidney and metabolism to the corresponding cysteine S-conjugates, may undergo bioactivation by renal cysteine conjugate beta-lyase. The beta-lyase-catalyzed beta-elimination reaction yields unstable thiols, which give rise to acylating agents and haloalkanoic acids; both the acylating agents and the haloalkanoic acids may contribute to the observed cellular and mitochondrial damage.

ABSTRACT: (U) Plant activation is the process by which promutagenic agents are activated into mutagens by plant systems. With the widespread use of agricultural chemicals on crop plants and with the global exposure of plants to pollutants, the possibility exists that plant-activated agents may be introduced into the human food chain. The plant cell/microbe coincubation assay uses cultured plant cell suspensions as the activating system and bacteria or yeast cells as the genetic indicator organism. After a treatment time, the microbes are plated on selective medium. In this way, the activation system and the genetic system can be independently studied. In addition the viability of the plant cells and the microbial cells can be independently determined so that the toxicity of a test agent can be evaluated. Using cytochrome P-450 monooxygenase, and peroxidase inhibitors we are studying the biochemical mechanisms of plant activation of environmental contaminants especially aromatic amines. We developed a model of the TXI-cell activation of aromatic amines. The model integrates our data into a mechanistic framework and serves as a foundation for new experimental designs. The model has seven components. They are, (1) the aromatic amine (R-NH2) is transported into the plant (TXI) cell, (2) TXI intracellular peroxidase oxidizes the molecule (R-NH2OH),

ABSTRACT: (U) Over the past few years, a number of researchers have presented algorithms for computing the aspect graph representation for polyhedra and curved-surface objects. However, currently it is computer from the theoretical standpoint of perfect resolution in the viewpoint, the projected image and the object shape. This means that the aspect graph may include details that an observer could never see in practice. This paper reviews a complete implementation of an algorithm to compute the exact aspect graph of solids of revolution under the perspective projection in 3D space. The we explore the notion of introducing scale into the qualitative aspect graph framework, this providing a mechanism for selecting a level of detail that is large enough to merit explicit representation. Several alternative interpretations of the scale space aspect graph are examined in response to the results produced for an example object by the implemented system.

ABSTRACT: (U) Hydrazines are toxic compounds which have numerous military and industrial applications including their use in missile propellants and advanced aircraft such as the F-16 and space vehicles. Because of the recurrent exposure due to routine storage use and disposal of these compounds, understanding their toxic effects on the nervous system is important in the aerospace field. Toxic exposure to hydrazine can result in status epilepticus and eventual respiratory collapse. Acute hydrazines exposure can produce repeated tonic-clonic seizures in animals and man. This project has continued to direct its effort in understanding the molecular mechanism by which hydrazines may produce their neuronal excitatory effects. We have continued and expanded our investigation of the effects of hydrazine on specific electrophysiological properties on identified neurons in the invertebrate *Hermisenda crassicornis* and have expanded these studies to investigate the effects of hydrazine on isolated neurons in culture. Our studies have documented that hydrazine increase neuronal excitability in the LP-1 neuron of this nudibranch mollusc. Studies have been directed at further establishing the technical capability of investigating the effects of hydrazines on the rate of sustained repetitive firing. It has been shown that hydrazines increase the rate of sustained repetitive firing in this system. Studies have also been initiated to elucidate the

ABSTRACT: (U) The goals of the research are to study neural systems involved in the production and inhibition of fear and anxiety. Previous research has found that the acoustic startle reflex is sensitive to both fear and stress. Many effects produced by fear or stress are mimicked by infusion of the peptide corticotropin releasing factor (CRF) directly into the brain. This year we have found that infusion of CRF into the brain causes a pronounced, dose-dependent enhancement of the acoustic startle reflex in rats. This excitatory effect was blocked by a CRF antagonist or by lesions of the amygdala, a brain structure known to be involved in fear and stress. The present data indicate that the amygdala is part of the neural circuitry required for CRF to elevate startle. Because startle is mediated by a well-defined neural pathway, CRF-enhanced startle is a useful behavioral assay to analyze the neural systems upon which exogenous CRF acts to produce its behavioral effects. Startle, Fear, Stress, Amygdala, Corticotropin releasing fact.

ABSTRACT: (U) The area comprising southwestern New Mexico and southeastern Arizona has experienced a complex tectonic history. In particular, the period of time from the late Cretaceous to the present has brought varying degrees of compression, magmatic activity, uplift and extension. Three major provinces that developed as a result of this tectonism are the Colorado Plateau, Basin and Range and Rio Grande Rift. The Colorado Plateau is a region which is uplifted and relatively undeformed with respect to surrounding provinces. It is characterized by gently dipping strata that have undergone minor folding and warping, volcanism, and epeirogenic uplift during Cenozoic time. To the west, south and southeast, the Colorado Plateau is bounded by the Basin and Range and Rio Grande Rift extensional provinces. They have undergone extensive deformation and volcanic activity during the past 40 Ma, with signs of active tectonism continuing to the present.

ABSTRACT: (U) This technical program constitutes a theoretical research investigation of the electronic structure of atomic and molecular ions and of radiative and collisional processes describing their formation and/or destruction. This study is directed toward elucidating the structure of both thermodynamically stable cations and anions, and resonance or metastable excited states in such systems. In addition, this study will include an analysis of the effects of both static E-fields and time dependent laser fields on resonance excitation, stimulated autodetachment and radiative electron attachment processes in negative ion systems and ion-pair production in Rydberg atom collisions. The goals of this research program are to develop accurate computational techniques which are applicable to studies of the electronic structure and radiative properties of small atomic and molecular ions and to carry out detailed calculations of the structure of several prototype species, including light element alkalis, alkaline earths and the noble gases. It is anticipated that the results of this program will furnish fundamental data and provide a better understanding of several detailed experimental studies that are currently in progress in this area.

UNCLASSIFIED REPORT

ABSTRACT: (U) A theoretical and computational investigation of the inviscid Kelvin-Helmholtz instability of a two-dimensional fluid sheet is presented. Both linear and nonlinear analyses are performed. The study considers the temporal dilatational (symmetric) and sinuous (antisymmetric) instability of a sheet of finite thickness, including the effect of surface tension and the density difference between the fluid in the sheet and the surrounding fluid. Previous linear-theory results are extended to include the complete range of density ratios and thickness-to wavelength ratios. It is shown that all sinuous waves are stable when the dimensionless sheet thickness is less than a critical value that depends on the density ratio. At low density ratios, the growth rate of the sinuous waves is larger than that of the dilatational waves, in agreement with previous results. At higher density ratios, it is shown that the dilatational waves have a higher growth rate. The nonlinear calculations indicate the existence of sinuous oscillating modes when the density ratio is of the order of 1. Sinuous modes may result in ligaments interspaced by half of a wavelength. Dilatational modes grow monotonically and may result in ligaments interspaced by one wavelength. Atomization, Liquid Surface Instability, Kelvin-Helmholtz Instability.

UNCLASSIFIED REPORT

ABSTRACT: (U) The major effort of this project was field data collection, data processing, and interpretation for the PACE (Pacific to Arizona Crustal Experiment) seismic experiment. This major cooperative study involved the University of Texas at El Paso, the Air Force Geophysical Lab, the U.S. and Canadian Geological Surveys, Stanford University, the University of Saskatchewan and the University of Arizona. The massive data set gathered during this experiment have been analyzed by a variety of techniques. The results show a gradual thickening of the crust from about 30 km in the Basin and Range to about 40 km along the southwestern margin of the Colorado Plateau. Lateral variations along the transition zone were found to be small. Work along a long profile extending from the Nevada Test Site to White Sands Missile Range included collection of new data, waveform modeling of data from the Albuquerque, NM digital seismograph station and a crustal structure study of western New Mexico. These results document thin (approximately 35 km) crust beneath the central portion of the Rio Grande rift, extension of the lithospheric anomaly associated with this rift well east of the physiographic rift valley, a broad transitional zone to thick crust on the western margin of the rift, and delineation of a batholithic mass in the upper crust of western New Mexico, Colorado Plateau.

ABSTRACT: (U) Results are presented from an experimental study of the molecular mixing of a dynamically passive conserved scalar quantity in an axisymmetric laminar vortex ring. The experiments are based on highly resolved laser-induced fluorescence imaging measurements of the scalar field (x, t) in the diametral plane of the ring, from which the evolution of the molecular mixing rate field (x, t) can be directly examined. In particular, the structure and dynamics of the mixing process are addressed during the three characteristic stages in the ring evolution, namely, (1) the ring generation stage, (2) the ring pinch-off stage, and (3) the asymptotic stage of the ring. Results show a layering of the mixing process in which the diffusional cancellation term plays a major role in setting the overall mixing rate achieved. The scalar field measurements are also used to extract detailed information about the underlying velocity field in the ring. Turbulent flows, Reacting flows, Fine scale structure, Mixing.

ABSTRACT: (U) The reaction of atomic hydrogen with isocyanic acid (HNC0) to produce the amidogen radical (NH2) and carbon monoxide, (2(a)) H + HNC0 - NH2 + CO has been studied in shock-heated mixtures of HNC0 dilute in argon. Time-histories of the ground-state NH2 radical were measured behind reflected shock waves using cw, narrow-linewidth laser absorption at 597 nm, and HNC0 time-histories were measured using infrared emission from the fundamental U2-band of HNC0 near 5 Am. The second-order rate coefficient of reaction (2(a)) was determined to be: $k_{2a} = 2.1 \times 10^{-10} \exp(-8500/T.K)$ ($f = 0.5, F = 1.75$) T = 2340-3270 K, cm3 mol-1 s-1, where f and F define the lower and upper uncertainty limits, respectively. An upper limit on the rate coefficient of (5) NH + HNC0 - NH3 + NCO was determined to be: $k_5 < 5.0 \times 10^{-10}$ cm3 mol-1 s-1 T = 2340-2680 K. Shock tube, Hydrogen, Isocyanic acid, Reaction.

ABSTRACT: (U) The evolution of an imperfectly mixed system-mimicked in terms of a distribution of lamellae-is studied. Two reactants A and B, initially placed in alternate striations, diffuse and undergo a reaction $A + B \rightarrow 2P$ with intrinsic rate $r=k$. (CACB) a Simulations, scaling analysis, and space-averaged (fractal) kinetics are used to study the evolution of the system for different values of a and k . For $a = 1$ and short times, a model based on the dynamics of reaction for a single lamella with infinite neighbors predicts the overall rate of reaction. For $a < 2.5$, diffusion takes control of the dynamics for moderate to large times, and the kinetic parameters become irrelevant. Under these conditions, critical self-organization determines the behavior of the system, and the spatial structure evolves into a self-similar form that is independent of both k , and initial conditions. En route to scaling, the system undergoes two independent transitions: (1) from intrinsic chemical kinetics control to diffusion control, and (2) from a system with several characteristic lengths to a system with only one characteristic length; these transitions might occur in any order, depending on controlling parameters. A combination of both short- and long-time regimes gives an efficient prediction for the average concentration of

UNCLASSIFIED REPORT

ABSTRACT: (U) Patterns of 40 to 80 Hz oscillation have been observed by researchers of this laboratory in the large scale activity not only of olfactory cortex, but also* visual neocortex, and shown to predict the olfactory and visual pattern recognition responses of a trained animal. Similar observations of 40 Hz oscillation in auditory and motor cortex, and in the retina and EMG have been reported. It thus appears that cortical computation in general may occur by dynamical interaction of resonant modes; as we have long thought to be the case in the olfactory system. The oscillation can serve a macroscopic clocking function and entrain or bind the relevant microscopic activity of disparate cortical regions into a well defined phase coherent collective state of gestalt. This can override irrelevant microscopic activity and produce coordinated motor output. We have further evidence that the oscillatory activity is roughly periodic, but actually appears to be chaotic (nonperiodic) when examined in detail. If this view is correct, then networks with oscillatory and possibly chaotic activity form the actual cortical substrate of the diverse sensory, motor, and cognitive operations now studied in static networks. It must then be shown how those functions can be accomplished with oscillatory and chaotic dynamics. It is our expectation that nature makes good use of this dynamical complexity, and our intent has

ABSTRACT: (U) Methods were developed for recording from locus coeruleus (LC) neurons in behaving monkeys using a microwire electrode holder allowing easy electrode repositioning in vivo. These techniques have vastly improved our data collection, so that we now routinely record from over 100 LC neurons per animal. Recordings of individual neurons are stable for periods of 30 min to 4 h. Methods were also developed for computer presentation of stimuli and task control in an oddball visual discrimination task. Other development included computer methods for data acquisition and analysis (on a separate machine) during this task. Results indicated that most LC neurons are activated selectively for target stimuli during this task; they are not activated appreciably by nontarget stimuli. In addition, preliminary results suggest that tonic LC activity varies closely with the animal's attentiveness to the task. These results indicate that very small changes in the tonic discharge rate of LC neurons may produce marked changes in attentiveness, and that focused, attentive behavior may demand an intermediate level of LC discharge combined with robust phasic responses to meaningful sensory stimuli.

ABSTRACT: (U) An integral method is presented for determining the evolution of molecular mixing, finite rate chemical reactions, and local extinction in diffusion layers under the effect of an unsteady strain rate. The partial differential equations governing the reactant, product, and temperature profiles are used to derive ordinary differential equations governing the evolution of moments for the product and temperature profiles and for the reactant gradient profiles. The actual profiles enter these equations only through integral moments resulting from the reaction rate terms (referred to as reaction integrals). As a consequence, it is possible to accurately track the evolution of the profile moments, and thereby determine global properties of the layer such as burning rates and extinction conditions, using remarkably simple representations for the actual profiles to evaluate the reaction integrals. Here these profile shapes are specified as self-similar families of curves parameterized by just a few degrees of freedom, which then evolve from the moment equations. Results for combustion in isolated strained diffusion layers, as well as for consumption of a burning fuel strip, are generally within a few percent of the results from finite difference solutions of the full equations.

ABSTRACT: (U) Line-of-sight measurements of velocity, temperature, pressure, density, and mass flux were performed in a transient shock tube flow using three laser absorption schemes. All methods employed an intracavity-doubled ring dye laser tuned to an OH transition in the A2 Sigma+ - X2 pi (0,0) band at 306 nm. In the first scheme, the gas was labeled by 193.3-nm excimer photolysis of H2O, and the passage of the generated OH was detected downstream. In the second method, the laser was tuned at a rate of 3kHz over the R1(7) and R1(11) line pair, and absorption was simultaneously monitored at 90 and 80 deg with respect to the flow. Velocity was determined from the Doppler shift of the profiles and the temperature from the intensity ratio of the lines. Pressure was determined from both the magnitude of absorption and the collisional broadening. In the third method, the laser wavelength was fixed at a single frequency, and a continuous measurement of velocity and pressure was obtained using the signals from the two beam paths. All methods gave results which compare favorably to calculated values. Velocimetry, Flow, Temperature, Mass Flux, Shock Tube, Laser.

ABSTRACT: (U) 'Me reactions of CH and C-atoms with N₂, which are believed to be initial steps in the prompt-NO mechanism, were studied at high temperature behind reflected shocks. CH was formed from the pyrolysis of highly dilute mixtures of CH₄ or C₂H₄ (<30 ppm) in argon. C-atoms were formed by pyrolysis of dilute mixtures of C₃O₂ in argon. 'Me on rates were determined from measurements of CH, C-atom and N-atom concentrations. CH was detected by cw, narrow-linewidth laser absorption of 431.131 nm. C-atoms and N-atoms were detected using atomic resonance absorption (ARAS) at 158.1 nm and 119.9 nm, respectively. Pyrolysis of C₃O₂ in the presence of excess N₂ resulted in rapid C-atom removal due to C(3P) + N₂ - CN + N, (1) leading to k₁ = 6.3 x 10¹³ exp(-23160 K/T) (+ or 30%) cm³ mol⁻¹ s⁻¹ over the temperature range 2880 to 4880 K and pressure range 0.5 to 1 atm. In order to determine the rate coefficient of CH(X²) + N, - HCN + N, (2) a perturbation technique was employed. In this technique, the CH profile resulting from pyrolysis of CH₄ or C₂H₆ dilute in argon was perturbed by the addition of N₂. A detailed analysis of the CH profiles led to a rate coefficient, k₂ = 4.4 x 10¹² exp(-11080 K/T)(+ or - 50%)

ABSTRACT: (U) The effect of the velocity ratio across an axisymmetric, thick bluffbody separating an inner jet from an outer annular confined stream on the flow dynamics is investigated using results of vortex simulations at high Reynolds number. The shear layer between the recirculation zone and the annular flow exhibits low amplitude oscillations characteristic of Kelvin-Helmholtz instability. On the average, two counter-rotating eddies and two stagnation point are found on the inside the recirculation zone. Both forms of unsteadiness arise due to intrinsic shear flow instabilities triggered by random perturbations in the flow field. Bluffbody, Velocity Ratio, Vortex Simulation.

ABSTRACT: (U) The subject of the research is detection and estimation employing an array of sensors. Of particular concern is efficient and numerically reliable computational strategies for implementing prevalent detection/estimation procedures. A number of important array processing problems lead to a differencing of matrix outer products. This leads to potential ill-conditioning when implemented explicitly. The avoidance of outer products, at the expense of extra operations, has long been a crusade of sorts in the numerical analysis community (Golub). One can do without outer products by means of orthogonal, or for complex data unitary, transforms in the usual case where a sum of outer products arise. (Typical transforms that have been found to be particularly useful are Givens, Jacobi, and Householder transforms). The idea is to transform the data into sparse form while preserving its pertinent statistics (usually the sample covariance matrix). This research concerns generalizing this 'trick' to the case of a difference of outer products by means of hyperbolic, rather than orthogonal transforms.

ABSTRACT: (U) Results are reported for a three year research program with the goal of generating high power microwaves over long-pulselengths. Three types of cyclotron maser devices were developed and utilized in experiments on the Michigan Electron Long Beam Accelerator, (MELBA) at electron beam parameters of 0.6-0.9 MV, 0.52-2 kA, and 0.5-5 microsec: (1) The gyrotron backward-wave-oscillator, (gyro-BWO) produced the optimal combination of high power (1-8 MW) and long pulse (0.5-1.2 microsec) microwave generation. Due to these promising results, this gyro-BWO device was investigated most intensively during the final phase of this research program. (2) Bragg resonator cyclotron resonance masers were investigated with high quality, low current electron beams for high frequency microwave generation. These devices generated hundreds of kW for hundreds of ns but it was found that microwaves originated from cyclotron harmonic generation on absolute instabilities. (3) Open cavity resonators of unslotted and slotted types generated microwave spikes (20-40 ns) in the X-band with peak power up to 15-25 MW. High peak microwave power (MW) was also generated in the K-band, most likely from the second cyclotron harmonic.

ABSTRACT: (U) Progress is reported for the past year of an interdisciplinary program aimed at establishing advanced optical diagnostic techniques applicable to combustion gases and plasmas, with some emphasis on high speed flows. The primary flowfield parameters of interest are species concentrations (including electrons), temperature, mass density, pressure, and velocity, and quantities derivable from these parameters such as mass flow rate (from the product of density and velocity). The techniques under study are based on laser spectroscopy, particularly laser absorption and laser-induced fluorescence, with the latter capable of providing both single-point and multi-point (2-d and 3-d) measurements. Laser sources include tunable cw lasers (ring dye and semiconductor diode lasers) and tunable pulsed lasers (excimer-pumped dye and narrow-linewidth excimer). The cw lasers are spectrally narrow, allowing study of a new class of techniques based on spectral lineshapes and shifts, while the pulsed lasers provide intense bursts of photons needed for techniques based on light-scattering phenomena. Accomplishments of note include: the first optical measurement of mass flux in high speed air flows; the first applications of tunable semiconductor diode lasers to absorption and fluorescence measurements in

UNCLASSIFIED REPORT

ABSTRACT: (U) The quantitative prediction of the dynamics of separating unsteady flows, such as dynamic stall, is of crucial importance. This six-month SBIR Phase I study has developed several new pressure-based methodologies for solving 3D Navier-Stokes equations in both stationary and moving (body-comforting) coordinates. The present pressure-based algorithm is equally efficient for low speed incompressible flows and high speed compressible flows. The discretization of convective terms by the presently developed high-order TVD schemes requires no artificial dissipation and can properly resolve the concentrated vortices in the wing-body with minimum numerical diffusion. It is demonstrated that the proposed Newton's iteration technique not only increases the convergence rate but also strongly couples the iteration between pressure and velocities. The proposed hyperbolization of the pressure correction equation is shown to increase the solver's efficiency. The above proposed methodologies were implemented in an existing CFD code, REFLEQS. The modified code was used to simulate both static and dynamic stalls on two- and three-dimensional wing-body configurations. Three-dimensional effect and flow physics are discussed. UNCLASSIFIED REPORT

ABSTRACT: (U) The crucial component needed to understand molecular reactions is the potential energy surfaces (PES) that serve to describe the attractions among the atoms and molecules. However, such information is not easy to obtain. In many cases, the most direct approach to obtaining accurate potential surfaces for molecules, and detailed information about their excited states, vibrational spectra, and a wealth of other quantities, is high level ab initio solutions of the Schrodinger equation. However, more so than in most other areas, the ability to provide reliable quantum mechanical results for increasingly large molecules depends critically on improved method development. Whereas supercomputers can enable us to make much larger computations with old methods, the simultaneous development of new methods can increase computational capability by further orders of magnitude. In this regard, many-body perturbation theory (MBPT) and its infinite-order extensions termed coupled-cluster (CC) methods offer a number of attractive features that the more traditional configuration interaction approaches lack. Under AFOSR support, we have established these CC/MBPT theories as being among the most accurate available, and have developed very efficient and generally applicable computer programs to perform CC/MBPT calculations. Also, we have employed

ABSTRACT: (U) A network has been established that measures and records electric fields in a 800 Hz to 3.5 MHz 3dB bandwidth at five stations at Kennedy Space Center. Signals were recorded at the central station with a 20 MS/s digitizing system that operating on a 24 hour per day basis. Data has been obtained from both lightning and small discharges that do not fit the commonly accepted definition of lightning. These small discharges frequently precede the first cloud-to-ground flash in a storm and are the most significant finding in the research so far. They have considerable importance in the field of thunderstorm electrification in that they predominantly occur below the freezing level, at a mean height of about 3-4 km.

UNCLASSIFIED REPORT

ABSTRACT: (U) Dications possess unusual electronic structures and bonding configurations. They display high energy releases and thus may serve as prototypes for molecular systems which have enormous energy per unit mass. This program combines a parallel experimental and theoretical approach to the study of gaseous molecular dication species. This includes spectroscopy, kinetics and reactions, and high level electronic structure calculations. Broad survey calculations with complete active space self-consistent field (CAS-SCF) wavefunctions have been carried out to characterize many of the hydride, fluoride, and oxide dication species. Highly accurate multireference configuration interaction (MR-CI) wavefunctions have established the electronic structures and stabilities of species such as CF2+, F22+, HS2+, NF2 2+, N2 2+, C2 2+, and PH. Vibrational and rotational constants, tunneling lifetimes, and transition strengths are obtained, providing to the experimental studies. Reactive studies have been carried out in a crossed beam arrangement on CO2+, NO2+, and HC with rare gases, and hydrogen. Selective product channels are observed and cross sections obtained. High resolution

ABSTRACT: (U) Four kinds of investigations of the structure of high-level visual processing were conducted during the past year. First, we carried out case studies of individual brain-damaged patients, finding evidence that curved edges are processed separately from straight edges, that location information sometimes can be used to encode some characteristics of shape, and that a decrease in overall activation level can selectively impair performance on some tasks. Second, we administered a set of 27 tasks to a group of 17 brain-damaged patients; these tasks were designed to assess the efficacy of specific subsystems. We have preliminary evidence that most (89%) of the subsystems double dissociate-suggesting that these subsystems are in fact distinct. Third, we constructed computer simulation models to explore properties of the high-level visual system, and found support for the distinction between subsystems that compute two distinct kinds of spatial relations. Finally, some of the tasks we had developed to study deficits in brain-damaged patients were used to study the visual-spatial abilities of air force pilots; we found that pilots are particularly good at mental rotation and encoding metric distance information. UNCLASSIFIED REPORT

ABSTRACT: (U) This report summarizes the major research accomplishments performed under AFOSR Grant 99-0231, HUMAN IMAGE UNDERSTANDING. An extensive series of experiments assessing the visual priming of briefly presented images indicate that the visual representation that mediates real-time object recognition specifies neither the image edges or vertices nor an overall model of the object but an arrangement of simple volumes (or geons) corresponding to the object's parts. This representation can be activated with no loss in efficiency when the image is projected onto the retina at another position, size, or orientation in depth from when originally viewed. Consideration of these invariances suggests a computational basis for the evolution of two extrastriate visual systems, one for recognition and the other subserving motor interaction. The experiments suggest that it may be possible to assess the functioning of these systems behaviorally, that is, to split the cortex horizontally, through a comparison of performance on naming and episodic memory tasks. We have developed a neural network model (Hummel and Biederman, 1992) that captures the essential characteristics of human object recognition performance. The model takes a line drawing of an object as input and generates a structural description which is then used for object classification.

AD-A247 048

AD-A247 048

UNCLASSIFIED

PAGE 97

T85004

The model's capacity for structural description derives from its solution to the dynamic binding problem of neural networks: Independent units representing an object's parts (in terms of their shape attributes and interrelations) are bound temporarily when those attributes occur in conjunction in the systems input.

UNCLASSIFIED REPORT

ABSTRACT: (U) Over the period of the AFOSR grant we have made significant progress in clarifying the relationship between the noradrenergic system and IEG expression in the brain. A series of studies has been performed in which the effects of activation of the noradrenergic system by drugs or stress on activation of the IEG response was examined. Results strongly suggest that the noradrenergic system is involved in the activation of IEGs caused by physiological as well as pharmacological agents. Whether this is the only neuronal system involved is not yet clear as stress, yohimbine and propranolol are known to affect other neurotransmitters and their receptors in the brain. This problem will be addressed in future research. In conjunction with our biochemical studies of noradrenergic neurotransmission we have also sought to identify the postsynaptic cells in which these biochemical events occur so as to facilitate studies of long term changes caused by stress. We have made substantial progress in this area and have obtained evidence that there are 2 separate target cells, a glial cell in which cyclic AMP is synthesized in response to beta receptor activation and a neuronal cell in which the immediate early genes are produced again in response to beta receptor activation.

UNCLASSIFIED REPORT

ABSTRACT: (U) To examine the effects of sweepback on the unsteady separation in Mach 5 compression ramp interactions, fluctuating wall pressure measurements have been made upstream of the corner line in interactions generated by unswept, and 10, 20, 25, 30, 40, and 50 deg. swept models. The streamwise ramp angle was 28 deg. in all cases. The data were analyzed using standard time series analysis techniques and condition all sampling algorithms. The results show that: (1) In highly swept interactions (i.e., corner line sweeps greater than 25 deg.), the rms distributions of pressure fluctuations as well as the mean distributions are quasi-conically symmetric. Rms levels decrease globally with increasing sweep as does the maximum rms generated by the translating separation shock. (2) The length of the intermittent region, over which the separation shock foot translates, decreases with increasing sweep. In a given interaction, the length of the intermittent region grows spanwise. (3) Dominant separation shock frequencies, observed in both surface pressure fluctuations and separation shock foot histories, increase from about 0.3-0.5 kHz for unswept flow to about 2-7 kHz in highly swept flows. In a given interaction, shock frequencies decrease spanwise. (4) Separation shock dynamics defined in terms of the shock foot history and its statistics are

AD-A247 035

AD-A247 035

UNCLASSIFIED

PAGE 101 T85004

essentially the same in all interactions. The separation shock foot position is normally distributed, and the mean shock velocities are essentially equal. The only difference is in the length of the region in which the separation shock moves. Higher frequencies are a direct result of the decrease in the length scale of the separation shock motion. Shock Wave Boundary Layer Interaction, Unsteady Flow, Separated Turbulent Boundary Layers.

UNCLASSIFIED REPORT

ABSTRACT: (U) This final report documents the results of a basic research program aimed at (1) studying the high temperature failure mechanisms in ceramics, (2) establishing relationships between cavitation mechanisms and creep crack growth characteristics, and (3) developing a damage mechanism-based life prediction model. The growth rate, near-tip creep responses, and damage processes of creep cracks in a pyroceram glass-ceramic were studied under tensile loading at elevated temperatures. The results of these studies indicated that creep crack growth in the pyroceram glass-ceramic occurred both in continuous and discontinuous manners, with the damage processes manifested as the nucleation, growth, and coalescence of inhomogeneously distributed cavities and microcracks. Sintering of cavities led to the existence of a growth threshold below which the creep crack would open, blunt, but not propagate. Measurements of the total accumulated creep strain near the crack-tip revealed that creep crack extension followed a critical strain criterion. Relationships between cavitation mechanisms and creep crack growth characteristics of the glass-ceramic are discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) Research has been performed to determine fundamental properties of negative ions; decay mechanisms and products of molecular Rydberg states; and mechanisms affecting H- production in ion source discharges. Experiments were performed on both stable and metastable states of Ca-, Cs-, He 2-, and W03-; on the dissociative decay of Rydberg states of H3, D3, D2H, H2D, NeD, NH, CH, and O2; on the product states of dissociative recombination of Ar2 and Kr2; and on the vibrational distribution of O2+ resulting from the reaction O+ + CO; yields O2+ + CO. Negative Ions, Molecular Rydberg States, Predissociation.

UNCLASSIFIED REPORT

ABSTRACT: (U) The basic aims of this research program have been to study the mechanical properties and constitutive relations of granular materials that support the applied loads through interparticle frictional contacts, and to relate these to the granular fabric, both stress-induced and inherent. To this end a coordinated experimental and theoretical program was followed in order to identify: (1) effective parameters that measure the fabric of granular masses; (2) the difference between inherent and induced fabric, and the influence of each on the constitutive response of the material; (3) parameters which measure the evolution of fabric in the course of a given overall load or deformation history; (4) the relation between fabric and the overall stress and deformation, and (5) constitutive relations which directly involve fabric measures and the measure of their evolution, and hence, are based on the fundamental n-microstructural events which give rise to nonlinear material response. Fabric, Stress, Deformation, Granular, Materials.

ABSTRACT: (U) Implementation of three algorithms, (1)
moment equation, (2) Monte Carlo, and (3) quantum
Liouville equation algorithms, were used in a program to
determine the high speed and high frequency operation of
submicron electron devices. For a pseudomorphic high
electron mobility transistor, high frequency, small
signal, subpicosecond charge density waves were observed
to form within the two dimensional electron gas. Large
signal operation of the PHEMT indicated that the
switching time of the device was governed by the longest
relaxation effect, the energy relaxation time, estimated
to be longer than two picoseconds. A simple two terminal
device configuration was examined. It was determined that
measurements of its transient behavior, would expose
differences in the key relaxation times governing III-V
device behavior, and provide the first direct measurement
of nonequilibrium effects in 'semiconductor' devices.
Transient instrumentation, Simulation, Speed, Two-
dimensional pseudomorphic HEMT, Picosecond.

UNCLASSIFIED REPORT

ABSTRACT: (U) Venous air embolism (VAE) is a potentially fatal occurrence frequently encountered in neurosurgical procedures performed in the sitting position. The morbidity of this event has been reduced primarily by efforts at early detection and prevention. Clinically, VAE is accompanied by hypoxia, hypercarbia, and an increase in dead space, manifested initially by a precipitous fall in end tidal carbon dioxide (ETCO2). Treatment consists of identifying and controlling the source, and hyperventilation on 100% oxygen. Hemodynamic support is given as required. A canine model of VAE was used to evaluate the effect of different inspired gas mixtures on the recovery from continuous venous air infusion. Sulfur hexafluoride (SF6), a non-hyperoxic, nitrogen free inspired gas was tested to determine if it would be a preferable alternative to recovery on 100% oxygen. Residual air effect was identified after the recovery period by a nitrous oxide challenge. In this study, recovery from VAE on 100% oxygen, as determined by response to nitrous oxide, was demonstrated to be significantly superior to either room air or SF6. ETCO2, pulmonary artery diastolic pressure (PAD) and arterial oxygen tension (PaO2) all demonstrated a greater ability to tolerate the nitrous oxide challenge in subjects

UNCLASSIFIED REPORT

ABSTRACT: (U) One of the most interesting properties of neural networks is their ability to learn appropriate behavior by being trained on examples. Established learning algorithms which typically work by minimizing error through backpropagation in weight space, tend to get stuck in local optima--a tendency typical of gradient-descent methods applied to nonconvex objectives functions. Therefore, for problems of nontrivial complexity these systems must be handcrafted to a significant degree, but, the distributed nature of neural network representations make this handcrafting difficult. We are investigating an evolutionary approach to learning that will avoid this problem. This approach simulates a variable population of networks which, through processes of mutation, combination, selection, and differential reproduction, converges to a group of networks well suited to solving the task at hand. The role of the different genetic operation, e.g., recombination and mutatio was also studied. We use a Connection Machine to exploit the inherent parallelism in these simulations. UNCLASSIFIED REPORT

ABSTRACT: (U) This work involves theoretical analyses of turbulence in high speed flow and large eddy simulation results for the mixing layer. Analysis indicates that turbulence is dominated by streamwise vortices as the Mach number approaches infinity. A conceptual model based on swept vortices makes predictions about the sweep angle of these vortices from spanwise at low speeds to streamwise at high speeds, and about the reduced spreading rate at high speeds. Simulations of planar shear layers, started from random initial disturbances, validate these structural predictions. Some interesting characteristics about high speed turbulence have been identified. Shocks are generally rare and weak, even at a convective Mach number of 2.5, because the flow normal to the swept vortices is subcritical. The turbulence kinetic energy is dominated by streamwise fluctuations, while the other energy components are much smaller. The pressure velocity correlations promote weak transfer of energy from the streamwise fluctuations to the other components of energy, and they strongly suppress the shear stress. These statistics are, in general, compatible with the swept vortex structure of turbulence at high Mach number. Compressible turbulence, Flow simulation mathematical models.

ABSTRACT: (U) Planar laser-induced fluorescence imaging of the hydroxyl radical (OH) is used to investigate spatial structures in a number of highly turbulent (ReD - 2300 to 50,000) nonpremixed hydrogen jet flames burning in air. Hydroxyl marks the flame zone and is also expected to mark large vortical structures in the flame. At each experimental condition, more than 80 OH images are recorded within 8 seconds, permitting the compilation of statistical measurements at more than 120,000 spatial locations. Several image analysis techniques are presented. Each technique is applied to individual images within a data set, and then statistics are compiled for the complete set. Two-dimensional Fourier transform techniques are used to calculate spatial autocorrelations on each instantaneous image, from which length scale information is extracted. Two orthogonal correlation lengths are determined for each image. The correlation length along the flame exhibits a Reynolds number invariance for high ReD (>2 x 10 to the 4th power). The autocorrelation technique also produces a clear, mathematically-defined flame angle. The measured flame angles indicate increased angular fluctuation of the jet at high Reynolds number. The dependence of lift-off

AD-A246 981

ABSTRACT: (U) Mixtures of NO and C₂H₆ in Ar were shock-heated and then photolyzed with an ArF excimer laser. Measurements of N-atom profiles using atomic resonance absorption spectroscopy (ARAS) permitted determination of the rate coefficient for the reaction N + CH₃-H₂CN + H (1) over the temperature range of 1800 to 2000 K, with the result: $-k_1 = 7.1 \times 10$ to the 13th power (+/- 35%) CM₃ mol⁻¹ s⁻¹. No significant temperature dependence was observed. This reaction plays an important role in the formation of HCN in rich flames. To our knowledge, this is the first N-atom/hydrocarbon radical rate coefficient to be measured at high temperatures. Shock Tube, Reactions, Resonance Absorption, N-Atoms, Methyl Radicals

ABSTRACT: (U) The reactions of C atoms and CH with NO, which are believed to be initial steps in the NO reburning reaction mechanism, were studied at high temperature behind reflected shock waves. C atoms were formed by pyrolysis or photolysis of dilute mixtures of C₃O₂ in argon or by pyrolysis of dilute mixtures of CH₄ in argon. CH was formed from the pyrolysis of dilute mixtures of CH₄ or C₂H₆ (<30 ppm) in argon. C atoms were detected by use of atomic resonance-absorption (ARAS) at 158.1 nm. CH was detected by CW, narrow-line-width laser absorption at 431.131 nm. In the presence of excess NO, C atoms formed by pyrolysis or photolysis rapidly were removed by C(3p) + NO - products (1). A first-order kinetic analysis led to a rate coefficient $k_1 = 4.8 \times 10$ to the 13th power (+ or - 445%) cm₃ mol⁻¹ s⁻¹ over the temperature range 1550-4050 K and pressure range 0.5-1 atm. In order to determine the rate coefficient of CH(X²II) + NO - products (2), a perturbation technique was employed. In this technique, the CH concentration profile resulting from pyrolysis of CH₄ or C₂H₆-diluted in argon was perturbed by the addition of NO. A detailed analysis of the CH profiles led to the rate coefficient $k_2 = 1.0 \times 10$ to the 14th power (+ or - 50%) CM₃ mol⁻¹ s⁻¹.

1 over the temperature range 2570-3790 K and pressure range 0.8-1.1 atm. The product channels of reactions 1 and 2 were studied by measuring the formation of product species, CN, N atoms O atoms, OH, and NH, using laser absorption or ARAS. The branching ratios of the product channels of reaction 1, C(3P) + NO - CN + O (1a) and C(3p) + NO - CO + N (1b), are $k_{1b}/k_1 = 40\%$ and $k_{1b}/k_1 = 60\%$. Independent of temperature from 2430 to 4040 K.

ABSTRACT: (U) The effects of two adenosine diphosphoribose transferase (ADPRT) enzyme inhibitory ligands, 6-amino-1,2-benzopyrone and its 5-iodo-derivative, were determined in AA-2 and MT-2 cell cultures on the replication of HIV-1 IIIB, assayed by an immunochemical test for the HIV protein p24, and syncytium formation. Characteristic of HIV-infected cells. Intracellular concentrations of both drugs were sufficient to inhibit poly(ADP-ribose) polymerase activity within the intact cell. Both drugs inhibited HIV replication parallel to their inhibitory potency on ADPRT, but distinct differences were ascertained between the two cell lines. In AA-2 cells both p24 and syncytium formation were depressed simultaneously, whereas in MT-2 cells only syncytium formation was inhibited by the drugs, and the p24 production, which remained unchanged during viral growth, was unaffected. Both drugs only moderately depressed the growth rate of the AA-2 and MT-2 cells and there was no detectable cellular toxicity. Results suggest the feasibility of the development of a new line

ABSTRACT: (U) Results from highly resolved, four-dimensional measurements of the fine structure of the fully space- and time-varying $Sc \gg 1$ conserved scalar field and the associated scalar energy dissipation rate field in a turbulent flow are presented. The resolution achieved in all three spatial dimensions and in time reaches down to the local strain-limited molecular diffusion scale in the flow, allowing all three components of the instantaneous scalar gradient vector field $V(x,t)$ and their time evolution at every point in the data space to be directly evaluated. Results are presented in the form of fine structure maps of the instantaneous dissipation field $\log V(x,t)$ in several spatially adjacent data planes within an individual three-dimensional spatial data volume, as well as in several temporally successive data planes from a sequence of such three-dimensional data volumes. The degree of anisotropy of the underlying scalar gradient field is characterized in terms of the joint distribution $B(V,p)$ of spherical orientation angles. The probability density of true scalar energy dissipation rates is presented and compared with the distributions that would result from

ABSTRACT: (U) Sun-corona, Sun-flares, Sun Radio Radiation Imaging observations at decimetric and metric wavelengths of the solar corona are used to investigate a short-lasting noise storm and the associated changes in the underlying active region plasma. It is shown that a new source appears in the active region in close temporal and spatial coincidence with the onset of the noise storm in the middle corona. The onset of the noise storm is delayed at longer wavelengths. At a given wavelength, the noise storm undergoes a systematic slow movement with a significant component perpendicular to the magnetic field lines above the active region. The observations are tentatively attributed to the emission of nonthermal electrons in a system of expanding coronal loops, the expansion being initiated by the appearance of the new 21 cm source in the low atmosphere. The derived velocity of expansion is about 80 to 150 km/sec. It is shown that the electrons emitting the noise storm cannot be provided by the high-energy tail of the Maxwellian in the new active region source, but originate either from a nonthermal population in this source or from acceleration at higher altitudes, in the structures which give rise to the noise storm. The new source in the active region underneath the

ABSTRACT: (U) An experimental investigation was carried out to examine the effects of manipulator blades on the Reynolds-stress production process in the log layer of a turbulent boundary layer. A three-dimensional sampling grid was used to investigate the effect of manipulators on the ensemble-averaged velocities and pseudoinstantaneous distributions of the structures associated with Reynolds-stress producing events detected at the wall over the Reynolds number range $3400 < Re < 5200$. The effect of manipulators on the ejection frequency for $3000 < Re < 10,000$ was found to be small. Furthermore, a reduction of the three-dimensional structure was observed only for the larger scales associated with the production process, and a return to conditions equivalent to a regular boundary layer was documented over approximately 100 boundary-layer thicknesses downstream of the manipulators. The results suggest that the larger (outer) structures of boundary layers play only a partial role in the wall process and that this production process can be incipiently generated and self sustained. Turbulent Boundary Layer Control Reynolds Stress

ABSTRACT: (U) Most, if not all, cancer cells have some dysfunction in gap-junction-mediated intercellular communication, either because of defects in cell adhesion or inability to have functional gap junctional communication. In addition, most, if not all, tumor-promoting chemicals and conditions down-regulate gap junction function, while some antitumor-promoting chemicals can up-regulate gap junctional communication. Several oncogenes are associated with down-regulation of gap junction function and several hormone and growth regulators, known to be tumor promoters, are also able to down-regulate gap junction function. On the other hand, some tumor suppressor genes have been linked to the up-regulation of gap junctions. Based on these observations, it is hypothesized that, if a progenitor cell is unable to perform gap junctional intercellular communication, normal growth control and cell differentiation would not be possible, thereby favoring the development of malignant neoplasia.

ABSTRACT: (U) Reacting Jets, Lagrangian Simulation Vortex simulation, using the transport element method is used to study shear flow combustion interactions in a reacting jet at high Reynolds number. We use an unsteady, low-Mach number model of combustion in which exothermic energy deposition produces volumetric expansion and baroclinic vorticity while shear flow instability induces entrainment and a strong strain field. The numerical scheme is a Lagrangian, grid-free field method in which computations are confined to the vorticity, reacting zone. Solutions are obtained for a two-dimensional flow with a single step Arrhenius kinetics.

ABSTRACT: (U) The evolution of a one-dimensional array of reactive lamellae with distributed striation thickness is studied by means of simulations, scaling analysis, and space-averaged kinetics. An infinitely fast, diffusion-controlled reaction $A + B \rightarrow 2p$ occurs at the interfaces between striations. As time increases, thin striations are eaten by thicker neighbors resulting in a modification of the striation thickness distribution (STD). Scaling analysis suggests that the STD evolves into a universal form and that the behavior of the system at short and long times is characterized by two different kinetic regimes. These predictions are confirmed by means of a novel numerical algorithm. Mixing, diffusion, reaction

ABSTRACT: (U) This research grant used tunable vacuum ultraviolet radiation generated by four-wave mixing to probe collisional energy transfer, reactive encounters, and photodissociations. Translation-to-vibration/rotation energy transfer was examined in the $H + CO$ system to learn how the extent of transfer depends on the collision energy and to determine the vibrational and rotational distribution of the product. The quenching of $S(1D)$ by N_2 was studied to learn the branching ratio for quenching to each of the $3P_0$, $3P_1$ and $3P_2$ components as well as to determine the rates of equilibration among these components. Photodissociations of OCS , CO_2 , and C_3O_2 at 157 nm were studied to learn the distribution of energy in the S , O , and CO products and to investigate vector correlations and velocity distributions of these products. This integrated program of molecular dynamics studies using vacuum ultraviolet radiation has enhanced our knowledge both of the chemical physics of these basic processes and of the interaction of high energy photons with small molecules likely to be found in the upper atmosphere. Molecular dynamics, Lasers, Vacuum ultraviolet.

UNCLASSIFIED REPORT

ABSTRACT: (U) Our goal has been to understand visual cortical function using psychophysical techniques. In particular, we examined visual attention, visual search, visual surface representation and color filling in. In visual attention, we found evidence to suggest two components of focal attention, a transient and a sustained process. We also provided evidence for the role of attention in saccadic eye movements by showing rapid deployment of attention in the gap paradigm. In visual search, we found a particular situation where increasing distractor number led to decreasing reaction times, suggesting a different role for attention in such tasks. In visual surface representation, we outlined the role of surface encoding (border ownership, modal and amodal completion, transparency) in many visual tasks. From these studies we postulated the principle of generic image sampling, a hypothesis which provides a geometric tool to understand visual surface learning. We also have investigated the perception of depth from unpaired points (Davinci stereopsis), showing that such points lead to depth and subjective contours. In color filling in, we have explored spatial-temporal dynamics and have created a neural model.

ABSTRACT: (U) During this funding period, the macrokinetic theory for electron transport (developed for semiconductors during the previous funding period) has been implemented for multivalley semiconductor. The model has been applied to GaAs subjected to rapidly varying (in time) fields. The set of material parameters used has been obtained by minimizing the error between calculated and measured transport parameters over the range of values of applied field for which experimental results are available. An experimental facility for investigating the transient dynamics of high power semiconducting switches has been established.

ABSTRACT: (U) Experiments and analysis were completed concerning a diagnostic program on a two dimensional subsonic windtunnel with a backward facing step and combustion. Combustibles were introduced as a hydrogen-argon mixture from a porous floor behind the step. Completed were LDV and Raman spectroscopy for mean and rms velocity (two components) and temperature. Analysis used a two equation turbulence model which predicted the gross features of the flow but somewhat underpredicted reattachment length. Two dimensional and three dimensional fractal interpolation techniques were developed for reduction of noise to signal ratio in the complex turbulent flow. New methods of fractal analysis of time series were developed. Fractals, Turbulence, Combustion, Ramjet, Optics, Fluid Mechanics.

UNCLASSIFIED REPORT

ABSTRACT: (U) Our development of an ideal-observer framework and a test-pedestal methodology for modeling vision without the numerous assumptions of previous models has provided a comprehensive understanding of the spatio-temporal characteristics of human vision. The methodology encompasses a limited set of test stimuli with a multiplicity of pedestals to facilitate the comparison of performance across many psychophysical tasks. For example, it is shown that vernier acuity can generally be predicted from an individual's contrast discrimination threshold. For the conditions under which contrast discrimination predictions break down, a detailed modeling of later stages of visual processing is required. As a result, specifications for a vision modeling tool have been developed to guide the creation of a comprehensive vision modeling environment. As our models of visual function have matured, we have applied them to practical issues such as image compression and image quality. Consideration of properties of human vision is essential if the image compression needed for new technologies such as HDTV are to avoid sacrificing image quality. The success of the test-pedestal methodology has also lead us to record human visual evoked potentials so that we may integrate our psychophysical data and models of vision with underlying physiological mechanisms. ABSTRACT: (U) Perfluoro-n-decanoic acid (PFDA) effects on protein expression in the rat liver were studied in rodents following in vivo exposure to PFDA levels above, below and at the LD-50. Two-dimensional whole liver homogenate protein patterns were generated and compared to previous results. As before, numerous proteins were altered; some suppressed, some induced, but most were unaffected. In an effort to identify the altered proteins, further analysis of basic proteins by first-dimension NEPHGE revealed the induction of cytochrome P452 (lauric acid omega-oxidase) and enoyl-CoA hydratase. Induction of these and related enzymes confirms previously observed PFDA-induced peroxisome proliferation and lends strong support to the notion that PFDA blocks normal Beta-oxidation, causes fatty acid accumulation, and results in compensatory peroxisomal and mitochondrial omega-and Beta oxidation continued identification of other altered proteins will be undertaken to add to the metabolic paths affected by PFDA to further delineate its toxic mechanism.

UNCLASSIFIED REPORT

ABSTRACT: (U) The project reported here focuses on the regulation of neuronal sensitivity by a novel class of protein kinase: an ecto-protein kinase which phosphorylates proteins at the cell surface by extracellular ATP. We proposed that the ecto-protein kinase that our previous studies have described in neuronal cells may play a significant role in the regulation of neuritogenesis and synaptogenesis. Our studies are designed to provide experimental evidence in support of this hypothesis. The progress we have made, in this project includes the development of novel experimental paradigms for the determination of ecto-protein kinase and its substrates in cultured cells. We used these paradigms in the conclusive identification of the surface phosphoproteins in primary neurons cultured from embryonic brain and in PC12 cloned neuronal cells induced to differentiate by nerve growth factor (NGF). We have determined which of these surface phosphoproteins are regulated by NGF.

SUPPLEMENTARY NOTE: Original contains color plates: All DTIC/NTIS reproductions will be in black and white.

ABSTRACT: (U) A control system for the enhancement and regulation of mixing in a nonreactive plane shear layer has been developed in a two-stream closed-return water facility. Mixing of a passive scalar is estimated using a thermal analog in which two streams have uniform, steady temperatures differing by $\Delta T = 30^\circ\text{C}$. The position of the temperature interface between the two streams is measured by an optical sensor which is placed upstream of the initial rollup of the spanwise vortices. Downstream of this sensor cross-stream temperature distributions are measured with an array of 31 cold wire sensors. The actuators are a mosaic of surface film heaters flush mounted on the high-speed side of the flow partition. The degree of mixing between the two streams can be significantly varied with open-loop spanwise-uniform and nonuniform time-harmonic excitation. In closed-loop experiments and output from the interface position sensor is fed back to the surface heaters. These experiments indicate that feedback control of the motion of the temperature interface can be a powerful means of controlling entrainment by the spanwise vortices and

UNCLASSIFIED REPORT

ABSTRACT: (U) This project is part of an ongoing experimental analysis of the neural mediation of learning and memory. The overall objective is to document the learning-relevant dynamic physiological changes in brain circuit activities that mediate discriminative avoidance learning in rabbits. Electrophysiological multichannel recording of neuronal activity during learning in the behaving animal is a principal methodology. Important information is also provided by selective lesion-induced disruptions of neuronal circuit activity and behavior. The specific thrust of this project was collaborative, combining behavioral neurophysiology and receptor biochemistry in order to document learning relevant changes in neurotransmitter receptor binding correlated with learning-relevant neuronal activity. In addition, hypotheses of a theoretical model of the task-relevant information flow and neural circuit/network interactions were evaluated. In each of four behaviorally defined stages of acquisition, a distinct topographic distribution pattern of training-induced cue-elicited neuronal excitation was documented by recording the training-related neuronal activity in five nuclei of the anterior thalamus and in the four layers of the posterior cingulate cortex. Topographic patterns of training-induced binding of M2 acetylcholine and GABA receptors in the anterior thalamus correlated with the stage-

related topographic patterns of thalamic activity.
Effects of hippocampal and mammillothalamic tract lesions
and the properties of the topographic patterns themselves
fostered the hypothesis that the patterns are a product
of hippocampal efferent flow to cingulate cortex and
anterior thalamus which is essential for context specific
mnemonic retrieval.

ABSTRACT: (U) 8-Nitroso-1,2-benzopyrone, an oxidation
product of 6-amino-1,2-benzopyrone, binds to the DNA-
recognizing domain of the ADP-ribose transferase protein
and preferentially destabilizes Zn2+ from one of the two
zinc finger polypeptide complexes present in the intact
enzyme, as determined by the loss of 50% of 85Zn2+ from
the 85Zn2+-isolated protein molecule, coincidental with
the loss of 99% of enzymatic activity. The 50% zinc-
deficient enzyme still binds to a DNA template,
consisting of a 17-mer DNA primer annealed to M13
positive strand, resulting in the blocking of DNA
synthesis by the Klenow fragment of Pol 1. Auto-poly-ADP-
ribosylated ADP-ribose transferase, which is the
probable physiological state of this protein in intact
cells, does not bind to primer-template DNA and does not
block DNA synthesis by the Klenow fragment. On the basis
of this in vitro model it is proposed that molecules
which inhibit or inactivate ADP-ribose transferase in
intact cells can induce significant alteration in DNA
structure and replication.

UNCLASSIFIED REPORT

ABSTRACT: (U) A number of collaborative projects have been launched during the first year and a half of the grant. Consistent with the original proposal, the common theme to all these projects is the linkages between early sensory (psychophysical) processes and perceptual representations that provide access to cognition. The individual project are summarized in the body of the report. In addition to the research projects, two informal weekly seminars were held throughout the first year among Center personnel and those with closely related interests. One was concerned with the development of a front end for the kind of object recognition model described by RBC. The other was a general examination of recent research in neural net type models.

ABSTRACT: (U) An intracavity-doubled rapid-tuning cw ring dye laser was used to acquire fully resolved absorption profiles of NO line pairs in the A - X band at 225 nm at a rate of 4 kHz. These profiles were utilized for simultaneous measurements of flow parameters in the high speed 1-D flows generated in a shock tube. Velocity was determined from the Doppler shift measured using a pair of profiles simultaneously acquired at different angles with respect to the flow direction. Temperature was determined from the intensity ratio of the adjacent lines. Pressure and density were found both from the collisional broadening and the fractional absorption. From this information the mass flux was determined. The results compare well to 1-D shock calculations. Velocimetry, Flow, Temperature, Nitric oxide, Laser.

ABSTRACT: (U) The rate coefficients of the reactions (1) $\text{CN} + \text{O} - \text{CO} + \text{N}$ and (2) $\text{CN} + \text{O}_2 \text{ NCO} + \text{O}$ were determined in a series of shock tube experiments from CN time histories recorded a narrow-linewidth cw laser absorption technique. The ring dye laser source generated 388.44 nm radiation corresponding to the $\text{CN } B_2 + (v = 0) X_2 + (v = 0) P$ -branch enabling 0.1 ppm detection sensitivity. Reaction (1) was measured in shock-heated pa mixtures of typically 200 ppm N_2O and 10 ppm C_2N_2 in argon in the temperature range 3000 to 4500 K and at s between 0.45 and 0.90 atm. k1 was determined using pseudo-first order kinetics and was found to be $7.7 \times 10^{13} (+20\%) \text{ (cm}^3 \text{ mol}^{-1} \text{ s}^{-1})$. This value is significantly higher than reported by earlier workers. Reaction (2) was measured in two regimes. In the first, nominal gas mixtures of 500 PPM O_2 and 10 PPM C_2N_2 in argon were shock heated in the temperature range 2700 K to 3800 K and at pressures between 0.82 and 1.05 atm. k2 was determined by fitting the measured CN profiles with a detailed mechanism. In the second regime, gas mixtures of 500 PPM O_2 and 1000 PPM C_2N_2 in argon were shock heated in the temperature range 1550 to 1950 K and at pressures between 1.19 and 1.57 atm. Using pulsed radiation from an ArF excimer laser at 193 nm, a fraction of the C_2N_2 was photolyzed to produce CN. Pseudo-first order kinetics used to determine k2- Combining the results from both regimes, k2 was found to be $1.0 \times 10^{13} (+20\%) \text{ (CM}^3 \text{ mol}^{-1} \text{ s}^{-1})$.

ABSTRACT: (U) The evolution of a spatially-developing,
incompressible, inviscid, variable-density, confined
mixing layer is numerically simulated using the transport
element method. In this flow, vorticity is generated and
destroyed by the baroclinic torque, while the density
gradient changes according to the deformation imposed by
the flow map. Results show that density variation affects
the spreading rate of the layer, the phase speed of the
instability waves and the convective velocity of the
eddies, and alters the asymmetric entrainment patterns
observed in a uniform-density flow. The results are in
agreement with experimental and analytical results which
indicate that, at fixed velocity ratio, the spreading
rate (convective speed of the eddies) increases
(decreases) with increasing density ratio, and the
entrainment patterns become biased towards the low-
density side. Forced Shear Layer, Variable Density,
Variable Simulation.

ABSTRACT: (U) Computational studies of interactive, vaporizing droplets have been made in order to understand better dynamics of dense sprays. Axisymmetric situations with droplets moving in tandem and three-dimensional situations with droplets moving in parallel have been considered. Detailed velocity and thermochemical properties fields have been determined. Lift and drag coefficients, Nusselt numbers, and Sherwood numbers for the droplets have been obtained. Correlations of these numbers with instantaneous Reynolds number and transfer number have been obtained. The flow field has been solved by implicit finite-difference solutions of the Navier-Stokes equations. Explanations for the modifications of lift and drag forces, trajectories, and transport phenomena due to droplet interactions have been formulated. Results have been obtained for fuel droplets, especially in high temperature environments, and, to a limited extent, for liquid oxygen (LOX) droplets in a hot, reducing environment. The results, especially the correlations, should prove useful in spray modelling.

ABSTRACT: (U) Applications and properties of nonlinear optical materials were studied, especially photorefractive crystals. A summary includes: (1) Demonstration of a new technique for seeing an object buried in or behind a scattering medium using time-resolved holography in a spectral hole-burning material. (2) Demonstration of an all-optical switchboard using stimulated, mutually-pumped phase conjugation in a photorefractive crystal. (3) Use of optical novelty filters to detect small changes in an optical scene. (4) Invention of an electric field correlator to measure the coherence length of picosecond laser pulses, using two-wave mixing in a photorefractive crystal. (5) Derivation of a theory of beam coupling and pulse shaping picosecond light pulses in photorefractive crystals. (6) Development of a new, multiple level model to explain the nonlinear photoconductivity of barium titanate crystals. (7) Investigation of the role of absorption gratings in beam coupling in barium titanate crystals and showing how these gratings can conveniently be used to determine the density of charge in these crystals. (8) Explanation of how stimulated processes cause the curved beam paths observed in mutually-pumped and self-pumped phase conjugators.

ABSTRACT: (U) This project studied dissociative recombination of hydrogenic molecules H2(+) and H3(+). High lying Rydberg states were found to play a principle role in the determination of final products from dissociative recombination reactions essentially independent of reaction channel. These processes play important roles in the chemistry of volume H(-) ion sources. This is the simplest molecular ion and is amenable to accurate theoretical calculation provided the reaction mechanism is well understood. In H2+, the repulsive neutral state through which the recombination proceeds passes through the ion curve in the vicinity of the v=1 level.

ABSTRACT: (U) Scalar mixing and chemical reactions in
turbulent shear layers and jets are examined with
emphasis on experimental results of high spatial and
temporal resolution. Such measurements show that the
notion of distinguishing fluids that are molecularly
mixed from those that are simply stirred is valid and
useful. Two models that seem especially suitable for
implementing mixing analyses from this viewpoint are
described and speculations on possible connections with
the idea of chaotic advection offered. A primary
objective of this paper is to show that scalar mixing in
free turbulent shear flows is well described in these
terms and that it is the existence of large-scale
structures in these flows that makes such a description
useful. More specifically, evidence is cited showing that
large-scale motions associated with the structures lead
to mean concentration distributions that differ markedly
from those of the mean mixed fluid, and the overall
mixing rate is influenced by the value of the molecular
diffusivities even at what are considered to be high
Reynolds numbers.

ABSTRACT: (U) This is a first-year annual report on the project. The ultimate objective of this program is to develop a predictive reaction model for soot information in hydrocarbon flames. The specific objectives of the proposed 3-year study are to extend the modeling efforts to computer simulation and analysis of more complex sooting phenomena, such as sooting limits in laminar premixed flames, soot formation in premixed flames of aromatic fuels, and soot formation in laminar diffusion flames, and to further refine the underlying reaction mechanism of soot formation. During the first twelve-months period of the project, progress has been made in the following areas: development of a new optical model, simulation of sooting limits of laminar premixed flames; further development and testing of the detailed reaction mechanism for the formation and growth of polycyclic aromatic hydrocarbons (PAHs); and quantum-chemical potential energy calculations for ion molecule reactions.

1989. Available to DTIC users only. No copies furnished
by NTIS.

ABSTRACT: (U) The concept that glutathione S-conjugate
biosynthesis, which leads to mercapturic acid formation
and excretion, is an important mechanism of drug and
chemical detoxication is well established. Glutathione S-
conjugates are synthesized by the hepatic cytosolic and
microsomal glutathione S-transferases. The cytosolic
transferases are a family of homo- and heterodimeric
proteins with broad and overlapping substrate specificity
and at least 12 different subunits have been identified,
whereas the microsomal transferase is a single protein.
The glutathione conjugates are metabolized to the
corresponding cysteine S-conjugates by gamma-
glutamyltransferase (GGT) (EC 2.3.2.2.), aminopeptidase M
(EC 3.4.11.2), and cysteinylglycine dipeptidase (EC 3.4.
13.8), and the cysteine conjugates are acetylated by N-
acetyltransferase (EC 2.3.1.80) to form mercapturic acids.
Although most glutathione S-conjugates and mercapturic
acids are chemically stable, the formation of unstable
glutathione conjugates has been reported. For example,
glutathione conjugates of dihalomethanes are unstable and
yield formaldehyde as an observed product. The

ABSTRACT: (U) The increasing availability and use of advanced high tech human machine interfaces raise many interesting questions about what information should be presented to each sensory modality and how the information should be coded for a given modality. In this paper, attention is confined to the auditory component of the interface and, more specifically, to auditory localization. Both teleoperator systems and virtual-environment systems are considered, and attention is focused upon the opportunities and difficulties associated with the use of unnatural perceptual cues in these systems. Of central interest in this discussion is the use of such cues to improve resolution and thereby obtain systems with superlocalization capabilities. Advances in technology are creating major new challenges in the area of human machine interfaces and, in particular, the design of interfaces for teleoperator systems and virtual environment systems. In a teleoperator system, the human operator senses and operates upon a remote, inaccessible, or hazardous environment by means of a slave robot. Signals in the environment of the robot are sensed by devices on the robot, communicated back to the teleoperator interface, and displayed to the human operator; the responses of the

ABSTRACT: (U) Experiments and theory have produced a
reasonably good qualitative understanding of the
evolution of chaotic mixing of passive tracers,
especially in two-dimensional time periodic flow fields.
Such an understanding forms a fabric for the evolution of
breakup, aggregation, and diffusion-controlled reactions
in more complex flows. These systems can be viewed as a
population of 'microstructures' whose behavior is
dictated by iterations of a chaotic flow; microstructures
break, diffuse, and aggregate, causing the population to
evolve in space and time. This paper presents simple
physical models for such processes. Self-similarity is
common to all the problems; examples arise in the context
of the distribution of stretchings within chaotic flows,
in the asymptotic evolution of diffusion-reaction
processes at striation thickness scales, in the
equilibrium distribution of drop sizes generated upon
mixing of immiscible fluids, in the equations describing
meanfield kinetics of coagulation, in the sequence of
actions necessary for the destruction of islands in two-
dimensional flow, and in the fractal structure of

ABSTRACT: (U) Oxidized metabolites of 4, 4' - methylenebis (2-chloroaniline) (MBOCA) were tested for direct mutagenicity in a Salmonella typhimurium assay and for effects on gap-junctional communication of WB-F344 rat liver cells. The mutagenicities of the N-hydroxy, mononitroso and o-hydroxy (ring) metabolites of MBOCA were assayed without adding activating enzyme systems; using the frame shift sensitive strain TA98 and the base pair substitution sensitive strain TA100. The mutagenicity of the hydroxylamine was demonstrated by a linear increase in the formation of mutant colonies in both strains, with a formation of two revertants/nmol by TA98 and 21 revertants nmol by TA100. The mononitroso metabolite showed a slight positive effect on TA100, but effects were masked by its cytotoxicity towards this strain. This metabolite was neither mutagenic nor cytotoxic to TA98. The o-hydroxy and the dinitroso metabolites were negative for mutagenicity at concentrations up to 50 and 500 ug/plate, respectively. The effects of parent MBOCA and N-hydroxy, mononitroso and o-hydroxy metabolites on cell-cell communication were determined by a scrape loading/fluorescent dye transfer

ABSTRACT: (U) Spinal trigeminal nucleus pars oralis (Spov) is anatomically linked to brain circuitry thought to subserve unconditioned and conditioned nictitating membrane responses in rabbit. Single unit recording from Spov and adjacent reticular formation obtained during conditioning from awake, behaving animals revealed modulation of unit firing related to CS, US, and CR occurrence. Spov participates directly in the unconditioned response and probably relays US information to other brain areas subserving conditioning. The presence of CR related activity suggests that Spov may participate in the CR motor output pathway, and may also provide CR-related information to cerebellum. Sensory convergence and CR related activity in reticular formation mark this structure as a candidate locus of primary neuronal plasticity in this example of conditioning.

ABSTRACT: (U) It has been suggested that the maintenance of long term potentiation (LTP) in the hippocampal mossy fiber (MF) synapse involves a presynaptic mechanism that does not require the activation of protein kinase C (PKC), since this enzyme appears to be absent in the MF presynaptic terminals. In the present study the authors evaluated this proposal by directly comparing the metabolic properties of hippocampal MF synaptosomes and a conventional P28 synaptosomal preparation prepared from the same hippocampal tissue. Protein kinase C-dependent histone phosphotransferase activity was found to be comparable in MF and P28 synaptosomes. Western blot analysis was performed using antisera prepared against four of the PKC isoforms, and the results demonstrate that the δ , β , and γ PKC isoforms are present in relatively equivalent amounts in these two subcellular fractions. However, the cytosolic fraction derived from the hippocampal MF synaptosomes appeared to contain a greater amount of the PKC- ϵ isoform when compared to the P28 synaptosomal preparation. Four distinct endogenous substrates present in the MF synaptosomes are shown to be phosphorylated in response to PKC activation.

UNCLASSIFIED REPORT

ABSTRACT: (U) This document includes a detailed description of efforts to develop sol-gel polymer composites for use in the fields of electronics and photonics. The central aim of the SBIR Phase I effort was to develop a multifunctional composite containing both oxides and organic polymers; both of the components in these materials are expected to perform active roles. A particular example that was investigated is one in which the inorganic component increases the charge carrier mobility while an organic component enhances its nonlinear optical response. Another example is the potential of organic and inorganic semiconductors becoming redox-coupled creating an entirely new class of multifunctional materials. The work involved (1) the synthesis of several vanadium alkoxides and polymers, (2) developing protocols for the preparation of composite films of the highest optical quality, and (3) obtaining assessments of conductivity and nonlinear optical response. Spectroscopic data indicate the presence of specific absorption bands characteristic of charge transfer phenomena. High conductivity and a nonlinear optical response of the composites were observed. Further

ABSTRACT: (U) In superconducting thin films, the long range proximity effect and the observation of a novel resistance anomaly are new physical phenomena exposed through the development of a technique to precisely modify the transition temperature in a well defined region. Free standing metallic structures were fabricated to understand thermal transport in thin films. In this latter work, the electron-phonon interaction should be modified due to the thermal cut-off of excitations. Using two different techniques, we have determined that the electron-phonon interaction does not display the expected thermal cut-off, a fact which may be of significance in thermalizing electronic components. We have also observed a reduction of the electron-impurity-spin interaction due to size effects, which should have interesting consequences for the magnetism of ultrasmall structures.

ABSTRACT: (U) Gap junctional intercellular communication has been linked to the regulation of cell proliferation and differentiation. Since most normal mammalian cells have functional gap junctions while most malignant cells do not, it has been hypothesized that the carcinogenic process involves the inhibition of this important biological process. Using several in vitro assays (metabolic cooperation; Fluorescent Recovery After Photobleaching of FRAP; scrape loading dye transfer; and the cell mat assay), we have examined the effects of various oncogenes, chemical tumor promoters, and growth factors on gap junction function. Natural products (phorbol esters, teleocidin), drugs (phenobarbital), food additives (saccharin), solvents (heptanol), pollutants (PCBs, PBBs), pesticides and herbicides (DDT, 2,3,5-T), nutritional factors (unsaturated fatty acids), growth factors (EGF, TGF- β), metabolic byproducts (H₂O₂, cholesterol epoxides), oncogenes (src, ras), cigarette tar condensates, heavy metals (mercuric chloride), neurotoxins (dieldrin) and neurotransmitters (acetylcholine) have been shown to modulate gap junctional communication.

ABSTRACT: (U) Cesium, hydrogen and oxygen adsorption on beryllium clusters are studied using restricted Hartree-Fock (RHF) calculations and ab initio relativistic effective core potentials. The clusters are taken as cylindrical plugs from beryllium wafers. Cs(-), H(-) and O-to-substrate internuclear distances are optimized. For each system numerous low-lying electronic states are investigated and Mulliken electron populations analyzed. RHF calculations show that Be19, with three layers of atoms, is too small to adequately model the Be surface, while Be33, a five-layered system, and Be45, a seven-layered system, are more accurate representations of the bulk metal. The emitted electron is clearly seen as vacating a molecular orbital which is localized in the surface layer of the cluster, thereby giving further credence to the model. RHF calculations are completed for Pb1 and Bi1 semiconductor clusters. Blue shifts in optical spectra and geometry changes are shown to be due to quantum size effects. Scanning tunneling microscopy is used to investigate the nature of colloidal particles in the 15 nm diameter size range. Images show a near monodispersion of small gold clusters. A model of the STM tip as a polyatomic crystalline surface is shown to correctly explain observations of anomalous long range order.

ABSTRACT: (U) The Summer Faculty Research Program (SFRP) provides opportunities for summer research at Air Force laboratories in the physical sciences, engineering, and life sciences. The program has been effective in providing basic research opportunities to the faculty of universities, colleges, and technical institutions throughout the United States. The program is available to faculty members in all academic grades: instructor, assistant professor, professor, department chairman, and research faculty directors. It has proven especially beneficial to young faculty members who are starting their academic research programs and to senior faculty members who have spent time in university administration and are desirous of returning to scholarly research programs.

UNCLASSIFIED REPORT

ABSTRACT: (U) This research is based upon the hypothesis that three different phenomena - behavioural impairments after frontal lobe damage, 'general intelligence' or Spearman's g, and interference between dissimilar concurrent tasks-all reflect the operation of a central executive (CE) system involved in the organization of many different kinds of behaviour. Four sets of experiments are presented. One set shows the frontal lobe damage produces massive impairments in 'intelligence tests' based on current problem-solving ability. A second shows that one characteristic frontal error - mismatch between knowledge of a task's requirement and the resultant behaviour - can also be reliably produced in normals, and is closely related to g. The third set of experiments is based on the idea that executive processes lose importance as behaviour becomes stereotyped or automatic. If so, generating random sequences should load the CE, whatever their particular content, and the experiments indeed suggest that the demands of random generation are similar for verbal and manual materials. Similarly, the fourth set of experiments suggests that correlations between reaction time and g diminish with practice only if there are no switches in mental set. It is proposed that the CE is a system for detection/selection of goal states in novel behavioural settings.

ABSTRACT: (U) Comprehensive theoretical and experimental studies of the magnitude, sign, dispersion, and length dependence of the third order molecular susceptibility $\gamma_{ijkl}(-\omega_4; \omega_1, \omega_2, \omega_3)$ demonstrate that the microscopic origin of the nonresonant third order nonlinear optical properties of conjugated linear chains is determined by the effects of electron correlation due to electron-electron repulsion. Multiple-excited configuration interaction calculations of $\gamma_{ijkl}(-\omega_4; \omega_1, \omega_2, \omega_3)$ for the archetypal class of quasi-one dimensional conjugated structures known as polyenes reveal for the first time the principal role of strongly correlated, energetically high-lying, two photon $1A_g$ virtual states in the largest of the two dominant, competing virtual excitation processes that determine $\gamma_{ijkl}(-\omega_4; \omega_1, \omega_2, \omega_3)$. It is also found in studies of the effects of conformation on $\gamma_{ijkl}(-\omega_4; \omega_1, \omega_2, \omega_3)$ that the origin of the third order optical properties remains basically the same for the all-trans and cis-transoid polyenes, and the results for the two conformations are unified by a common power law dependence of the dominant tensor component $\gamma_{xxxx}(-\omega_4; \omega_1, \omega_2, \omega_3)$ on the physical end-

ABSTRACT: (U) Optical bistability is a quantum optical realization of a first order phase transition far from equilibrium. A nonlinear optical material contained in an optical cavity driven resonantly by an external coherent optical field undergoes a first order phase transition to a new nonequilibrium stationary state of broken symmetry. Resonant and nonresonant nonlinear optical response of pi-electron excitations in conjugated electronic structure provides the nonlinearity essential to the onset of bistability. Electronic correlation effects in reduced dimensions are responsible for nonresonant nonlinear optical responses. Saturable absorption studies of glassy polymer films consisting of quasi-two dimensional conjugated disc-like structure of silicon naphthalocyanine demonstrate that on-resonance the system behaves as an optical Bloch system with an intensity dependent refractive index of 10 to the -4 power sq cm per kilowatt. Based on the results of these studies, electronic absorptive optical bistability is observed on a nanosecond time scale in a nonlinear Fabry-Perot interferometer employing the saturable absorbing silicon naphthalocyanine film as the nonlinear optical medium.

UNCLASSIFIED REPORT

ABSTRACT: (U) The performance of ramjets burning slurry fuels (leading to condensed oxide aerosols and liquid film deposits), gas turbine engines in dusty atmospheres, or when using fuels from nontraditional sources (e.g., shale-, or coal-derived), depends upon the formation and transport of small particles across non-isothermal combustion gas boundary layers (BLs). Even airbreathing engines burning clean hydrocarbon fuels can experience soot formation/deposition problems (e.g., combustor liner burnout, accelerated turbine blade erosion and hot corrosion). Moreover, particle formation and transport are important in many chemical reactors used to synthesize or process aerospace materials (turbine blade coatings, optical waveguides,...). Accordingly, our research is directed toward providing chemical propulsion system engineers and materials-oriented engineers with new techniques and quantitative information on important particle- and vapor-mass transport mechanisms and rates. An interactive experimental/theoretical approach has been used to gain understanding of performance-limiting chemical-, and mass/energy transfer-phenomena at or near interfaces. This included the further development and exploitation of seeded laboratory flat flame burners, flow-reactors, and new optical diagnostic techniques. Resulting experimental rate data, together with the

UNCLASSIFIED REPORT

ABSTRACT: (U) Our goal is to quantitatively evaluate the concept of time-domain optical memory (TDOM) based on the stimulated photon echo technique and to prepare for the development of a working prototype. Earlier feasibility studies at SRI International showed that TDOM can store not only digital data in the form a series of on-off laser pulses but also two-dimensional (2-D) images with the same read/write speed. Despite work at SRI and elsewhere, until now the use of TDOM for 2-D images has not been carefully examined and the quality of echo images and their inherent spatial resolution have not been explored. These issues have an important bearing on TDOM as a high-speed, high-density storage device. This year, we focused on using the stimulated echo technique for 2-D image storage and image processing. Specific tasks included incorporating a gated intensified charge-coupled device (CCD) camera system for detecting echo images, digitally recording the echo images, and optimizing the optical system. We have also extended the earlier feasibility study on stimulated-echo-based, 2-D image storage and image processing and demonstrated storage and retrieval of the high-quality, high-resolution echo images. In addition, we demonstrated for the first time that nanosecond pattern recognition can be achieved using the stimulated echo approach. (Author)

ABSTRACT: (U) The main objective of this work is research and development of the theory and constructive computational algorithms for synthesis of single and dual reflector antenna systems in geometric optics approximation. During the reporting period the direct and inverse problems of design of reflector antennas were investigated. In case of single reflector antennas explicit conditions for solvability of the partial differential equation describing the system were established. An algorithm, based on a special diffusion process, for solving the equation numerically was developed and tested. Differential geometric methods were applied successfully to describe and investigate the single and dual reflector antenna systems.

ABSTRACT: (U) During the period of this grant the theory of superconductivity in high Technetium cuprates matured into a reasonable consistent, complete theory which has the capability, often realized, of confronting all of the puzzling experimental properties of the materials. During the period of the grant occurred the Cargese NATO Summer School (June 1990) attended by several of us who were being funded by the grant, and at that school I summarized progress up to that time. B. Doucot who had been one of our group was the local organizer. Perhaps the best summary of the situation at that time was given in my Chapter II setting out what I called the Central Dogmas of the theory, which is enclosed. At that meeting was formulated the justification of the Luttinger liquid hypothesis via a finite Fermi surface phase shift which led to several papers, especially the PRL and 'response' on the subject showing how the Fermi liquid theory breaks down.

UNCLASSIFIED REPORT

ABSTRACT: (U) Six separate projects have explored how velocity and acceleration are encoded in the human visual system. (1) Welch demonstrated speed discrimination for coherent plaid patterns formed of two superimposed gratings was limited by the speed of the gratings, not the apparent speed of the plaid itself. (2) Bowne et al. and more recently Grzywacz, applied 'motion-energy' models to the psychophysics of speed discrimination. (3) McKee and Welch compared the relative precision of velocity and size constancy, finding little evidence for velocity constancy in human motion processing. (4) Watamaniuk demonstrated that the visual system integrates diverse speeds (2-8 deg/sec) in a random dot display to obtain a precise estimate of the mean speed. (5) McKee and Watamaniuk found that a single point (the signal) moving in apparent motion (the noise), even though the spatial and temporal characteristics of the signal and noise points were identical on a frame-by-frame basis. (6) Bravo and Watamaniuk showed the two sets of randomly distributed dots moving in the same direction, but at two very different speeds, formed two transparent planes; discrimination of small changes in the speed of one set of dots was unaffected by the presence of the other dots.

UNCLASSIFIED REPORT

ABSTRACT: (U) This research program investigates the effect of extreme submicron and sub-100 nm spatial modulation of the electrostatic potential on the transport of electrons in heterojunction semiconductor devices. The test vehicle is the so-called periodic-gate FET (PGFET), with gate consisting of either a grating or a grid, of 200 nm periodicity. When electrons are made to move in a direction perpendicular to the potential modulation, i.e., perpendicular to the grating of along a grid axis, they exhibit a surface superlattice (SSL) effect. When moving along the potential modulation of a grating, electrons are restricted to only one degree of freedom and thus constitute a quasi-one-dimensional (Q1D) quantum system. Grid-gate FET's have been found to exhibit substantially stronger SSL Behavior than their grating-gate counterparts. Electron transport in quantized and spatially periodic systems have studied theoretically and new insights and quantitative calculations have been obtained. (Author)

ABSTRACT: (U) The objectives of this program were to investigate the relationships among phase equilibria, kinetics, mechanisms and microstructural development in chemically bonded ceramics which exhibit cementing properties. This objective was based on the need to identify the above relationships if advanced cement-based materials are to be developed. Although cements are normally regarded as civil engineering materials, this view is unduly limited. Emphasis in this program was on the broader objectives of near net shape fabrication at low temperature. The use of the term 'cement-based' is intended to imply that the reactions leading to microstructural development occur in an aqueous environment. Emphasis was on non-civil engineering materials, as such these materials are called chemically bonded ceramics.

ABSTRACT: (U) Our purpose is to identify those atmospheric conditions that lead to thunderstorm electrification. We have collected aircraft and radar measurements of atmospheric parameters made during several recent intensive field studies, and we are modifying our thunderstorm model to make it more realistic. The radar measurements will be used as inputs to the model and we will attempt in-cloud microphysical, dynamical and electrical behavior in a range of atmospheric environments. As our simulations evolve, we will examine the relationships between atmospheric sounding parameters and subsequent electric field development and we will classify soundings in terms of parameters relevant for lightning production.

ABSTRACT: (U) Research was conducted and directed in the area of stochastic processes and their applications in engineering, neurophysiology and oceanography. More detailed descriptions of the work of all participants is given in the main body of the report: Sampling designs for time series; Signal quantization; Wavelet approximation of random signals; Gaussian and non-Gaussian processes; Nonstationary processes; Exchangeable processes; Random fields; Point processes and random measures; Nonlinear filtering; Infinite dimensional stochastic differential equations; Stochastic partial differential equations; Random measures associated with high levels; Limit theorems for random measures; Parameter estimation under dependence.

DESCRIPTORS: (U) ESTIMATES, MATHEMATICAL FILTERS, NEUROPHYSIOLOGY, NONLINEAR SYSTEMS, OCEANOGRAPHY, PARAMETERS, PARTIAL DIFFERENTIAL EQUATIONS, QUANTIZATION, SAMPLING, SIGNALS, STATISTICAL PROCESSES, STOCHASTIC PROCESSES, TIME SERIES ANALYSIS.

IDENTIFIERS: (U) *Stochastic processes, *Applied mathematics, Engineering, Neurophysiology, Oceanography, Time series analysis, Parameters, Estimates, PE61102F, WJAFOSR2304A5.

ABSTRACT: (U) The United States Air Force Summer Faculty Research Program (USAF-SFRP) is designed to introduce university, college, and technical institute faculty members to Air Force research. This is accomplished by the faculty members being selected on a nationally advertised competitive basis for a ten-week assignment during the summer intersession periods to perform research to Air Force laboratories/centers. Each assignment is in a subject area and at an Air Force facility mutually agreed upon by the faculty members and the Air Force. In addition to compensation, travel and cost of living allowances are also paid. The USAF-SFRP is sponsored by the Air Force Office of Scientific Research.

UNCLASSIFIED REPORT

ABSTRACT: (U) Spatial light rebroadcasters (SLRs), consisting of thin films of luminescing electron trapping materials, are explored for digital optical computing. The status of optical computing is reviewed briefly. SLRs are characterized in detail: fabrication, sensitivity, linearity, speed, resolution, and modulation. A number of optical experiments are described that were conducted to determine the device effectiveness, applications for which the devices are best suited, and the direction for research to develop more useful devices. Optical experiments with basic SLR modules include a cascadable module, binary matrix-vector multiplier, and correlator. The basic modules were then used in memory, adder, interconnection, and learning experiments. These experiments show that the SLR has potential for digital optical computing, particularly where high density long term storage is required. However, the lack of gain, incoherent output, and lot output signal, means that other collaborative devices are needed which limit the performance. Future directions are discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) This is the second annual report of a project for investigating the laser induced CVD growth of AlN and Gallium Nitrogen. In the second year significant progress has been made in the growth of AlN. AlN films have been produced by laser ablation. A new LI CVD source for Al atoms has been characterized and verified by growth of Al films. Additionally, some progress has been made in the understanding and characterization of alkyl aluminum-amino adducts which may be used for the growth of AlN. The goal of this project is to design, test and verify advanced laser induced chemical vapor deposition processes (LI-CVD), specifically for the growth of AlN. In the past year we have made progress in three areas: (a) Rapid growth of AlN thin films by laser ablation of AlN powders. (b) Demonstration of an advanced LI-CVD method for deposition of Al from trimethylaluminum (TMA1). This method was designed to be used as the aluminum atom source in AlN growth, but also has utility for laser deposition of aluminum interconnects, an area of current interest. (c) Synthesis and characterization of a number of stable alkyl aluminum-nitrogen containing adducts for future use in film growth. We have grown Alkylaluminum nitrogen thin films by laser ablation of powdered Alkylaluminum nitrogen compressed into a pellet.

UNCLASSIFIED REPORT

ABSTRACT: (U) Three research issues are addressed: (1) establishment of a mechanism of chemical healing of microcracks within the process zone preceding the macrocrack, (2) establishment of the mechanism or mechanisms of relaxation and creep in asphalt cements of various types and (3) establishment of a formal tie between permanent strain in asphalt concrete and cyclic loading and the creep compliance function. A methodology has been developed by which to quantify the degree of fracture healing that occurs in asphalt concrete. The methodology has been verified by testing thirteen different asphalts with widely varying compositions and chemistries. This method of establishing the amount of fracture healing that occurs in asphalt concrete as the result of rest periods is being used to establish the microstructural mechanism responsible for fracture healing. Rheo-optics and infrared analysis using a Fourier transport infrared spectrometer are being used to establish the microstructural composition of asphalt cements that influence or control the creep, relaxation and fracture healing processes.

UNCLASSIFIED REPORT

ABSTRACT: (U) Acoustic mode combustion instability has long plagued the solid propellant industry, and the increasingly frequent requirement for 'reduced smoke' propellants, with concomitant removal of metals from the propellant formulations (and, thus, removal of metal oxide particulate products, which have a major role in damping of acoustic oscillations) is expected to exacerbate this problem. One strategy for alleviating the problem involves identification and utilization of approaches to decreasing a major source of acoustic energy, namely, the transient burning rate response of the solid propellant to pressure and/or crossflow velocity oscillations. Previous preliminary modeling studies have indicated that it might be possible to decrease the pressure coupled response functions of composite propellants by suitable modification of the relative activation energies of the fuel and oxidizer ablation processes.

ABSTRACT: (U) Integrated Guided-Wave Optics has many advantages for the analog processing of optical wavefronts. These include small-size, high-speed, simplicity, reliability and reproducibility. The fabrication technique is similar to that of integrated circuits. The thrust of this program is to develop an integrated guided-wave optic system, in GaAs and GaAlAs for use at GaAs laser wavelength, to remove aberrations from a laser beam and to steer the beam. The system would in addition have the capability to appropriately phase the outputs from a multiplicity of power amplifiers or injection-locked lasers. It is also the intent of the program to design and build the optical circuits so they are compatible with on-chip electronic circuits in order to minimize the required number of off-chip leads.

UNCLASSIFIED REPORT

ABSTRACT: (U) Solar disturbances produce major effects on the corona, the solar wind, the interplanetary medium, and the Earth along with its magnetosphere. We have developed new techniques for studying plasma disturbances in the inner heliosphere by remotely sensing them. These techniques use data from the HELIOS spacecraft zodiacal light photometers, the ISEE-3 spacecraft kilometer radio-wave experiment, and a variety of other spacecraft and ground-based instruments. The zodiacal light photometers on board the two HELIOS spacecraft (data coverage from 1974 to 1986) provide the first good information about the heliospheric masses and shapes of propagating disturbances. Metric and kilometer type II and type III radiation caused by shock waves and fast moving electrons respectively are another way to remotely sense the structures which propagate outward from the Sun. The best kilometer radio wave sensing of inner heliospheric plasma is available from the ISEE-3 spacecraft. The investigations into the physics of the disturbances sensed by these techniques and the ability to forecast their occurrences are well underway.

ABSTRACT: (U) The following findings were reported: (1) Oxtremorine-M binding in rabbit thalamus and cingulate cortex increased during discriminative avoidance conditioning (DAC). (2) Excitatory and discriminative neuronal activity was documented throughout DAC and there were relationships between training-induced neuronal activity and changes in binding. (3) Turnover of noradrenaline was significantly elevated during DAC suggesting a role for this transmitter in long-term memory. (4) Anterior cingulate cortex lesions uncover discriminative neuronal activity in the striatum and amplify activity in thalamus. (5) The structure connections and spontaneous activity of the lateral magnocellular nucleus in thalamus were described. (6) A review was written of the structure and function of cortical layer I and its role in learning and memory analyzed. These are the first studies to document physiological regulation of receptors and transmitters that occur during avoidance learning and provide the basis for a comprehensive analysis of the molecular bases for learning and memory.

ABSTRACT: (U) Observations have been made before and after a large solar flare. Magnetic features were observed that could be used to predict flares if they are a regular feature of such events. The observations were among the first to show the development of shear within one hour of flare onset. Observations of linear polarization have been made of transient brightenings at small points in the lower chromosphere. The association between these flare-like events and magnetic fields has been studied. A feasibility study has been made of observing the sun with a balloon-borne vector magnetograph. The APL vector magnetograph developed under an OSR URI is operational.

ABSTRACT: (U) In 1935, D. Burnett developed a higher order set of constitutive stress relationships from a class of solutions to the Boltzman equations. Our research on Burnett equations has identified five basic scientific issues in need of resolution before really satisfactory computations of 2D (or 3D) flow fields can be made with these equations. These issues relate to (1) surface boundary conditions, (2) frame independence, (3) material derivative approximation, (4) positive-definite dissipation (?), and (5) upper altitude limit for applicability. This report describes progress in areas 1, 3, and 4, and also an investigation of the interaction of a thick oblique shock impinging on a cowl lip in high-altitude hypersonic flow.

PAGE 174 T85004

ABSTRACT: (U) The goal of this program of research has been to specify auditory processing in the presence of noisy backgrounds. A variety of experimental and modeling approaches have been employed to examine this processing. Overall the results suggest the importance of spectral and temporal comparisons in signal detection and suggest that similar processing underlies monaural and binaural detection. The introduction of masker energy in temporal intervals that did not overlap with the signal could be shown to either enhance or degrade detection performance, depending on the interaural parameters of the stimuli. Experiments on remote masking and suppression showed excitatory and inhibitory effects that extended across more than an octave. These results are being used to evaluate a nonlinear model of cochlear processing. The responses of subjects to individual stimuli (reproducible noise samples) were highly correlated between monaural and binaural conditions that had seemed dramatically different when the ensemble performance was considered (i.e., data averaged across noise samples).

ABSTRACT: (U) This report summarizes the results of research conducted under AFOSR support with particular emphasis on investigations carried out during three-year period. The research reviewed includes homogeneous and heterogeneous processes of particular importance in the chemical vapor deposition (CVD) of silicon from silanes and disilanes, the study of chemical processes occurring under conditions of close confinement, non-statistical dynamics and intramolecular energy transfer processes. New methods for (1) obtaining potential energy surfaces for highly complex systems, (2) simulation of the effects of relaxation to the bulk in surface systems, (3) perturbation studies of gas surface scattering, (4) computation of two dimensional surface tunneling rates, (5) highly efficient variational phase space theory calculation of microcanonical unimolecular reaction rates, and (6) the computation of intramolecular vibrational relaxation rates are also described.

UNCLASSIFIED REPORT

ABSTRACT: (U) The structure and dynamics of inertia-gravity waves in the upper troposphere and lower stratosphere have been studied using data from a wind profiler that was temporarily located in Kansas, data from the Arecibo Observatory 430 MHz radar, data from the SIOS-VHF-Radar located in Germany, and data from the MU radar in Japan. The radar data has shown that low frequency inertia-gravity wave oscillations are a persistent feature of the region near the tropopause and in the lower stratosphere. Some of our analysis indicates that the wave structure is likely generated by the interaction of the surface winds and the orography. However, the frequency in the earth-fixed frame corresponds to a period of 24 hr and is not zero. The latter effect is presumably due to the strong vertical circulation near the tropopause with a reversal in direction at the height of the wind maximum. The observed vertical velocities are larger than expected but otherwise agree with the predictions of earlier theoretical analyses. We have also investigated the relationship between turbulent layers in the upper troposphere and lower stratosphere and the low-frequency inertia-gravity waves. The turbulent layers are observed to move in the same direction as the phase progression of the background waves, indicating that the turbulent layers occur at a particular wave phase where the wave-

UNCLASSIFIED REPORT

ABSTRACT: (U) This work focuses on examining the nature of the molecular beam epitaxial growth process, its control and optimization, achieving defect reduction via growth on prepatterned substrates, and the behavior of some optical and transport characteristics for strained system using InGaAs/AlGaAs as the vehicle. Highlights include (1) the first demonstration of GaAs(111)B homoepitaxy free of twins and with mirror-like surfaces through usage of real-time reflection electron diffraction intensity behavior; (2) demonstration of the presence of strain in the substrate to unexpectedly large depths below 3D islands of InGaAs; (3) presence of atomic relaxation in coherent islands; (4) the tendency for defect introduction at island edges beyond a critical size; (5) realization of strained InGaAs/AlAs resonant tunneling diodes with room temperature peak currents approximately 125 kAmp/sq cm and peak-to-valley ratios of 5:1; (6) defect reduction via strain relief at mesa edges in growth on prepatterned mesas; (7) realization of good electroabsorption in thick (1 to 2 microns) strained multiple quantum wells; (8) dielectric encapsulation induced strain shifts; and (9) rapid thermal annealing induced intermixing of components at interfaces and the resulting changes in the nature of the quantum well potential.

UNCLASSIFIED REPORT

ABSTRACT: (U) A scheme with the potential for generation of an electron beam with high brightness and several microsec pulse duration for microwave generation, electron accelerators or free electron lasers has been investigated experimentally. An electron beam was extracted transversely to the flow of a plasma jet. The transverse boundary of the plasma allowed extraction of a space charge limited electron current for 7 microsec at a brightness of 8×10 to the 8 th power a per sq. m per sq rad was achieved. Closure of the extraction gap by invasion of plasma has been observed with a velocity as low as 0.1 cm/microsec. Higher current density and higher brightness is expected for higher plasma densities and larger extraction fields. Numerical simulation using the MAGIC code confirmed the expected features of the scheme.

UNCLASSIFIED REPORT

ABSTRACT: (U) This work shows that units in the visual system are tuned to principal components of real world color natural images and provides insight on the strategy the visual system may be using to confront natural imagery. It is also useful for identifying image components that are significant for the visual system and those which it either keeps or enhances for later stages of signal representation and analysis. The methods by which retinal center/surround R/G type cells can be used to realize this coding system are also investigated. In collaboration with NASA, the properties of a number of natural spatio-temporal sequences was measured. We found that the sequences showed represents .98 of the signal energy as separable. In addition, we developed an efficient coding model for natural time varying imagery in the early visual system. We show that M and P channels conjoin with tracking eye-movement to make visual system retinal architecture matched to basic components of time varying imagery.

ABSTRACT: (U) Critical to the success of the Air Force Office of Scientific Research (AFOSR) mission is the ability of AFOSR to draw upon the research community in the United States to respond to its needs. In recent years, however, the number of U.S. citizens seeking advanced degrees in the areas of Air Force research interests has been decreasing. This refers specifically to the number of U.S. citizens obtaining Ph.D. degrees in areas of mathematics, science, and engineering that are of interest to the Air Force. This situation points toward the potential problem of a future shortage of qualified researchers in areas critical to the nation's security interest. To address this problem, the United States Air Force Laboratory Graduate Fellowship Program (USAF/LGFP) was established. The program annually provides three-year fellowships for at least 25 Ph.D. students in research areas of interest to the Air Force.

UNCLASSIFIED REPORT

ABSTRACT: (U) During the three years of this grant, a negative ion time-of-flight photoelectron spectrometer was constructed and used in a series of novel experiments designed to probe the transition state region in chemical reactions. In addition, conventional photoelectron spectra of several anions with high electron binding energies were obtained. Cold negative ions are produced in an ion source based on a pulsed free jet expansion. The ions are mass selected using a time of flight mass spectrometer. Ions of the desired mass are then photodetached with a pulsed, fixed-frequency laser, and the kinetic energy distribution of the ejected photoelectrons is determined by a second time-of-flight system. This allows us to map out the vibrational and electronic energy levels of the neutral species created by photodetachment of the mass-selected anions.

ABSTRACT: (U) Radar receiver and signal processing instrumentation was acquired and fabricated in order to establish a capability for dual 440 MHz and 1390 MHz radar operations at the M.I.T. Millstone Hill research facility. Hardware costs for a duplicate of the MIDAS radar processor were provided. This instrumentation enables a program of simultaneous, high-spatial resolution dual frequency observations of non-thermal and coherent radar backscatter from ionospheric plasma waves and turbulence at both F and E region heights. Simultaneous operation of the fully steerable Millstone Hill UHF and L-band radars in the incoherent scatter mode addresses the spatial homogeneity and simultaneity of ionospheric effects and processes.

ABSTRACT: (U) Minorities have traditionally been underrepresented in the biomedical sciences. This is especially notable in disciplines that require graduate level training, such as toxicology. The Society of Toxicology has made significant efforts to interest minorities in toxicology by introducing the discipline to undergraduates. The outreach program, showed evidence of success. About 150 people, a 'standing room only' crowd, attended the Educational Program for Minority Students. At another session a number of minority scientists and graduate students presented posters of their research results to an audience of interested toxicologists, employers, and minority undergraduates. The provided opportunity for the audience to note the wide variety of speciality areas in toxicology in which minorities work and study. Interaction of the Society of Toxicology with travel awardees was continued after the annual meeting. By review of the program through use of a questionnaire. Further contact between SOT and these advisors is being maintained by placing them on the mailing list for the SOT Newsletter.

ABSTRACT: (U) The following is a list of the research supported by the Air Force grant during the period September 15, 1988, to September 30, 1991. Basically the research can be divided into five categories: (1) profile analysis research, (2) synchrony detection, (3) dynamic factors, (4) psychophysical methodology, (5) use of Dr. B. Berg's COSS technique to analyze profile experiments. Profile analysis continues to be our central research interest. The question is what are the factors that influence the human listener's ability to detect changes in a complex acoustic spectrum. Synchrony detection refers to the fact that correlation or synchrony between the envelopes of different spectral channels can be used as an important detection cue. Our interest in this area was initially stimulated by Dr. Virginia Richards.

ABSTRACT: (U) This report summarizes analysis and
results comprising both theory and experiments related to
modeling of interfaces between cement matrix and
aggregates. The model simulates accurately behavior under
complex two and three dimensional states of stress and
deformation, where tension-shear and compression-shear
conditions occur. The constitutive theory describes
fracture and slip of interfaces and adhesion, debonding,
and mobilized friction mechanisms are modeled. Fracture
energy release is used to control softening. Analytical
predictions of experiments compare well, and the model
has been implemented in nonlinear finite element analysis
codes.

ABSTRACT: (U) This research is investigating how well large networks that are built from neuron-like elements can be made to perform, and learn to perform, by giving them different types and amounts of built in structure, and the ability to learn by generating new nodes in additions to changing weights. Substantial improvements in both learning speed and performance have been achieved on both pattern recognition problems and a range of problems typically used to demonstrate the power of connectionist networks. In addition, a number of new micro-circuits and sub-networks have been specified with which more powerful and more flexible networks can be built. These include: Back-cycling nets that handle learning(along with many useful functions), rather than have that handled by the system that executes the net; Nets that handle symbols as well as numbers; and Micro-circuits for productions and perceptual transforms.

UNCLASSIFIED REPORT

ABSTRACT: (U) Avalanche upconversion dynamics and associated nonlinear optical response was also reported for the first time in Tm:YALO crystals at room temperature. The avalanche mechanism involves a cooperative down conversion (cross relaxation) step and is a promising method of pumping rare earth lasers at entirely new (diode compatible) wavelengths, corresponding to excited state absorptions rather than ground state absorptions. Quantum theory describing the threshold for photo-darkening and the role of energy migration in avalanches was developed, and semi quantitative agreement obtained with preliminary measurements of nonlinear susceptibilities. Cooperative dynamics in general, and avalanche dynamics in particular, were shown to furnish a promising new mechanism not only for solid state lasers but for nonlinear optical interactions as well, opening the door to practical signal processing and switching applications exploiting the low intensity thresholds of avalanche processes.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Original contains color plates: All DTIC and NTIS reproductions will be in black and white.

ABSTRACT: (U) The report documents accomplishments made toward understanding the fluid flow and heat transfer processes in gas turbines at the University of Minnesota over the past two years. The research is divided into three subtopics: studies of film cooling, airfoil surface heat transfer and endwall flow and heat transfer. Film cooling experiments show the effects of interaction among jets on curved surfaces and calculations show that parabolic techniques give accurate effectiveness predictions in regions away from injection holes. The surface heat transfer program showed that tripping the flow or roughening the wall has a clear effect near airfoil transition and separation points and that recovery from concave curvature is surprisingly slow. Endwall studies show flow visualization on the cascade endwall and the value of a fence on the endwall for rerouting the horseshoe vortex away from the suction wall.

UNCLASSIFIED REPORT

ABSTRACT: (U) Research during this past year has emphasized studies of plasmas properties and associated diagnostics, including nonequilibrium effects in so-called thermal plasmas. The present report discusses first measurements of the radiative source strength of air for temperatures in the range between 5000 and 7500K. To our knowledge these are the first measurements of this important property in this temperature range. The results are compared with a NASA computer code. Also described is a study of quenching effects on excited states of a nonequilibrium thermal plasma. These and companion measurements show that the common assumption of local thermodynamic equilibrium in plasmas at or about atmospheric pressure can be seriously in error and that as a result the reliability of many temperature measurements in such plasmas should be questioned. Contents: Measurements of the volumetric radiative source strength of an air plasma between 5000 and 7500K; and Electronic quenching of argon excited states in a non-equilibrium plasma at atmospheric pressure.

ABSTRACT: (U) The purpose of this grant has been to undertake research in the general area of adaptive-grid finite element methods in estimation and control problems. The overall goal has been to investigate adaptive gridding numerical algorithms and to develop a solid theory to handle the mathematical questions of convergence and stability which arise in the use of such algorithms. The P.I. has met this goal through the study of a number of adaptive-grid finite element methods for parameter estimation problems governed by distributed parameter systems. In addition, stability problems encountered in the implementation of such algorithms have led her to make extensive studies of the ill-posed nature of these problems. In particular, theoretical and numerical studies were undertaken concerning regularization schemes for a number of ill-posed estimation problems. Specific applications considered in this latter study include the inverse heat conduction problem and regularizing aspects of descent methods as used to minimize fit-to-data functions associated with linear estimation problems.

UNCLASSIFIED REPORT

ABSTRACT: (U) This research effort can be categorized into three major areas. Section 1 of the report summarizes research on continuous fiber reinforced ceramic matrix composites. A systematic investigation of the damage development and failure behavior of Nicalon silicon carbide fiber reinforced calcium aluminosilicate composites was first conducted through mechanical testing and microscopy. Then, an analytical effort was made to examine the fracture behavior and thermal shock resistance of continuous fiber reinforced ceramic matrix composites. Section 2 is on whisker and/or short fiber reinforced ceramic matrix composites. The effort included analytical modeling of crack deflection and creep behavior of whisker reinforced composites. Characterization of fracture mechanisms in whisker/short fiber ceramic composites at elevated temperatures, and experimental investigation of high temperature creep behavior of the SiC(w)/A/203 composite system. Section 3 is on processing. Two research efforts have been reported. In one, the kinetics of the chemical vapor infiltration (CVI) process for fabricating continuous fiber reinforced ceramic composites was modeled for both isothermal and forced CVI conditions. In the other effort, sol-gel processing route was used to develop three-dimensionally reinforced textile (woven and braided) ceramic composites.

ABSTRACT: (U) A general framework for shift register-based test response compressors was developed based on algebraic coding theory. It has advantages over Markov modeling in allowing exact computation of aliasing probability and extension to other forms of built-in self-test. The use of deBruijn graphs was adopted to studies of VLSI-based multiprocessor networks. These allowed derivation of lower bounds on VLSI layout areas and provided a method to meet those bounds. The graphs were extended to hyper-de Bruijn networks. Finally a design was produced for fault-tolerant testable RAM's (TRAM's).

ABSTRACT: (U) The proper orthogonal decomposition (POD) was used to test the hypothesis that there exist a set of functions which characterize a turbine stator exit flowfield and whose dynamics may explain some of the complex behavior in downstream blade rows. The decomposition was applied to three component triple-wire probe measurements of a large-scale annular stator model exit flowfield. This study represents the first application of the orthogonal decomposition to directly measured three component data, and one of the first applications to an applied engineering flow. The full three-component cross-spectral tensor was produced from simultaneous multipoint triple-wire probe measurements. The measurements were taken across one stator pitch, at the passage midspan, 10% axial chord downstream of the stator trailing edge. The resulting 1089 cross-spectral estimates were then decomposed to obtain the eigenspectra and eigenmodes of the midspan flowfield. In addition, the POD was applied to two subdomains of the passage flowfield in order to increase the convergence rate of the energy representation. The two subdomains were taken to be the wake and outer flow region because of the large difference in scales between those regions. The wake spanned approximately 20% of the stator pitch at the

UNCLASSIFIED REPORT

ABSTRACT: (U) This study examined the role of oxygen in the development of neuromotor dysfunction generated by temporary aortic occlusion in awake and anesthetized rabbit models of experimental spinal cord ischemia. Animals underwent 30 minutes of infrarenal aortic occlusion, via a pre-implanted aortic snare, followed by 15 minutes of reperfusion prior to treatment with one of three inhaled gas compositions: air (control), 100% oxygen (sea level oxygen), and 100% oxygen at 2.8 atmospheres pressure (hyperbaric oxygen). After the 90 minute treatment and at specific times thereafter, the animals hindlimb motor function was graded on a five point neuromotor index (4 = normal, 0 = total paralysis). Control animals were paralyzed after reperfusion but regained hindlimb neuromotor function within six hours after reperfusion and retained substantial hindlimb movement at 24 hours. However, both the sea level oxygen and hyperbaric oxygen groups failed to regain hindlimb neuromotor function within six hour and were totally paralyzed at 24 hours. Histopathological examination of the animal's spinal cord revealed good correlation between spinal cord damage and the clinical neurological outcome. In an alternative anesthetized model, hyperbaric oxygen treatment appeared to temporarily retard the post

reperfusion improvement in neuromotor function. This phenomenon was not accompanied by an increase in tissue lipid peroxidation but was accompanied by post treatment hyperemia of the affected spinal cord segments. These data support the notion that the degree of inspired oxygen tension in the immediate reperfusion period may play a role in the development of spinal cord reperfusion injury.

UNCLASSIFIED REPORT

ABSTRACT: (U) Advanced aerospace systems require low density materials with substantially improved high temperature mechanical properties and oxidation resistance. Metal matrices with ceramic reinforcements offer such potential. The primary objective of this research effort is to develop a scientific understanding of the nature and extent of interactions between these materials at high homologous temperatures. Part of this study is to understand these processes sufficiently well that diffusion barriers can be selected to control the interaction. Interfacial reactions of silicon carbides, aluminum oxides and silicon nitrides with selected high temperature metals have been studied at temperatures between 800 and 1200 C for various times. The metal include neodymium and tantalum strong carbide formers, cobalt, nickel, platinum, Ti3Al, and stainless steel. Reactions of the metals with SiC in this temperature range were extensive; various metal silicides, metal carbides, ternary metal-silicon-carbides, and unreacted carbon were formed as layered reaction products in the reaction zones. Thin films of Al2O3 in the 100 to 500 nm thickness range are shown to be effective in minimizing the reaction between Nb and SiC.

UNCLASSIFIED REPORT

ABSTRACT: (U) This research developed imaging polarimetry to study the propagation of polarized light in polarization based optical interconnects such as the ATF digital optical computer, and adapted polarization aberration theory and polarization ray tracing, to understand new classes of problems arising in optical systems for digital optical computing. An imaging polarimeter was constructed and calibrated at UAH under this contract. The output is a Mueller matrix image, a spatial representation of the polarization properties across a wavefront, typically as a function of field of view or pupil coordinate. With the imaging polarimeter, one can simultaneously balance the transmitted polarization between the top and bottom, left and right sides of a wavefront as one rotates tilts, or otherwise adjusts the polarization components. Imaging polarimeter was demonstrated to be a useful alignment tool and was used to characterize many polarizing elements such as polarizing beam splitters, linear retarders, and liquid crystals.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report describes research results on the design of feedback controllers for rapid slewing of flexible space structures, such as optical tracking systems. Two approaches evolved during this research. The first approach modifies the exact rigid-body time-optimal control so as to account for chattering near zero tracking error and robustness to flexible modes close to the controller bandwidth. Efforts to make this controller adaptive are also presented. The second approach uses a combination of feed forward trajectory generation with a standard linear feedback in the inner loop. The feed-forward generator is designed by solving a convex optimization problem which is an approximation to the time-optimal problem. The latter approach is effective for multiple input multiple output systems with independent actuator saturation constraints.

ABSTRACT: (U) The focus of this workshop was to address
some issues facing the experimental turbulence research
community, such as the question of it relevance to
advances in fluid mechanics, the role of computers and
instrumentation, finding sources, education, and faculty
development. The major concerns were identified, and
discussions were had to develop a strategy to guide our
future activities. About 50 research workers in
turbulence attended, from all aspects of turbulence
research, over a period of two and a half days.

UNCLASSIFIED REPORT

ABSTRACT: (U) This program has investigated the use of
limit cycles to represent and processing symbolic
information in the context of an inference machine. This
approach was proposed as a means of overcoming problems
with fault tolerance and relatively small space-bandwidth
products in current spatial light modulator (SLM)
technology. The program has focused on developing a
storage medium with many limit cycles (oscillatory modes)
available and a method for coupling the various modes in
a desired way. Because of their flexibility, neural
network ideas were used as the basis for the components
and algorithms developed. In the theoretical realm, the
program has had many accomplishments. First, the self-
oscillating neural network (SONN) model was developed and
characterized as the oscillatory medium. This model was
designed with optical spatial SLMs in mind and does not
require any training or programming. Furthermore, it is
highly tolerant of static parameter variations inherent
in the optics. Next, the spectral back-propagation (SBP)
training algorithm was developed with complete generality
as a means of forming the coupling trajectories. This
algorithm trains input-output sequences into a network
using an error criterion based on a Fourier series
decomposition of the sequences. The method allows the
interconnects to have trainable time delays in addition

UNCLASSIFIED REPORT

ABSTRACT: (U) We have successfully produced an optically triggered thyristor based in Gallium Arsenide, developed a model for breakdown, and are developing 2 related devices, including a Gallium Arsenide based static inductor thyristor. We are getting at the basic limitations of Gallium Arsenide for these applications, and are developing models for the physical processes that will determine device limitations. The previously supported gas phase work - resulting in the back-lighted thyatron (BLT) - has actually resulted in a very changed view of how switching can be accomplished, and this is impacting the design of important machines. The BLT is being studied internationally: in Japan for laser fusion and laser isotope separation. ITT has built a BLT that has switched 30 kA at 60 kV in testing at NSWC Dahlgren and the device is being commercialized by another American company. Versions of the switch are now being tested for excimer laser and other applications. Basically, the switch, which arose from pulse power physics studies at USC, can switch more current faster (higher di/dt), with less housekeeping, and with other advantageous properties. There are a large number of other new applications, include kinetic energy weapons, pulsed microwave sources and R.F. accelerators.

UNCLASSIFIED REPORT

ABSTRACT: (U) Four experiments addressing the role of attention in phonetic perception are reported. The first experiment shows that the relative importance of two cues to the voicing distinction changes when subjects must perform an arithmetic distractor task at the same time as identifying a speech stimulus. The voice onset time cue loses phonetic significance when subjects are distracted, while the F0 onset frequency cue does not. The second experiment shows a similar pattern for two cues to the distinction between the vowels /i/ (as in 'beat') and /I/ (as in 'bit'). Together these experiments indicate that careful attention to speech perception is necessary for strong acoustic cues to achieve their full phonetic impact, while weaker acoustic cues achieve their full phonetic impact without close attention. Experiment 3 shows that this pattern is obtained when the distractor task places little demand on verbal short term memory. Experiment 4 provides a large data set for testing formal models of the role of attention in speech perception. Attention is shown to influence the signal to noise ratio in phonetic encoding. This principle is instantiated in a network model in which the role of attention is to reduce noise in the phonetic encoding of acoustic cues. Implications of this work for understanding speech perception and general theories of the role of attention in perception are discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) Many important Hamiltonian systems have periodic solutions that are associated with symmetries of the equations. While it is well known that stationary solutions of a Hamiltonian system can be characterized as extrema of the potential energy, it is less widely appreciated that symmetry-related periodic solutions, or relative equilibria, can also be given a variational characterization, typically involving constraints. This variational characterization is important because if a periodic solution is associated with a constrained minimizer (in some sense), as opposed to merely being a stationary point, then a stability result is very often available. We are therefore left with the problem of characterizing those extrema of a constrained variational principle that are actually constrained local minima. It is shown how to apply the new results in the special context of Hamiltonian mechanics, and various stability and instability theorems are described. The machinery developed here can be viewed as an alternative to the energy-casimir and energy-momentum methods with the benefit that the necessary tests can be concretely and rigorously applied in several complex examples of physical importance.

UNCLASSIFIED REPORT

ABSTRACT: (U) In the fifth and final year of the program the research has completed defining data structures, object based programming style, and tools for a new flexible approach to scientific programming and problem solving. Problems of program complexity associated with changing models and physics as well as with joined and disjoint multiple independent patched mesh domain decompositions for treating complex geometries and resolving captured flow structures can be systematically organized within the context of the directed graph programming concept being explored. Problems and parts of problems having geometric connectivity or its analogs such as association, hierarchy or precedence relationships are naturally exhibited and easily debugged or modified in the graph. The solution of problems is literally to traverse the graphs. For the emerging prototype aerodynamic simulation facility, the graphs which are to control grid generation Navier Stokes solution procedures, and scientific graphics are to be constructed with a graphical editor hosted in high performance graphics workstations. The efficient global data structure for the system is a set of large linear arrays in which the data and parameterization associated with the independent quadrilateral blocks of mesh are sequentially stacked. The directed graph is to control procedures that point to and operate on the data

ABSTRACT: (U) In this report we summarize our accomplishments in the research program supported by Grant AFOSR-88-0032 over the period from October 1, 1987 to September 30, 1991. The basic scope of this program is the analysis, estimation, and control of complex systems with particular emphasis on (a) multiresolution modeling and signal processing; (b) the investigation of theoretical questions related to singular systems; and (c) the analysis of complex systems subject to or characterized by sequences of discrete events. These three topics are described in the next three sections of this report. A full list of publications supported by Grant AFOSR-88-0032 is also included.

ABSTRACT: (U) Critical to the success of the Air Force Office of Scientific Research (AFOSR) mission is the ability of AFOSR to draw upon the research community in the United States to respond to its needs. In recent years, however, the number of U. S. citizens seeking advanced degrees in the areas of Air Force research interests has been decreasing. This refers specifically to the number of U. S. citizens obtaining Ph.D. degrees in areas of mathematics, science, and engineering that are of interest to the Air Force. This situation points toward the potential problem of a future shortage of qualified researchers in areas critical to the nation's security interest. To address this problem, the United States Air Force Laboratory Graduate Fellowship Program (USAF/LGFP) was established. The program annually provides three-year fellowships for at least 25 Ph.D. students in research areas of interest to the Air Force. This report includes information on the following topics: Volatile Organic Materials in soil and Their Removal, Seismological Studies of Earth Structure, Cerebral Configurations of Parents and Siblings of Language Disordered Boys, Thermo Inelasticity, Theorems of Linear Systems, Feedback Stabilization in Deformable Tokamak Plasmas, Magnetosphere Ionosphere Coupling Measurements, and Analysis of Autonomic Activity During Motion Sickness.

ABSTRACT: (U) Models of Turbulent Boundary Layers used the proper orthogonal decomposition theorem to provide optimal bases for finite dimensional subspaces so that relatively low dimensional projections of the Navier-Stokes equations can be calculated. These dynamical systems retain key features of the turbulence production mechanisms. The inherent symmetries from physical space which lead to the existence of structurally stable heteroclinic cycles, in turn creating intermittent dynamics remarkably similar to the bursting phenomenon observed in experiments. Ours are perhaps the first rationally derived low (-10-50) dimensional models for turbulence in open flows and they offer promise of improved understanding of basic mechanisms and design of drag control strategies. Unlike other groups using Karhunen-Loeve methods, we have carried out rather complete analyses of the projected ODE's. This work resulted in papers and also led to the mathematical questions.

UNCLASSIFIED REPORT

ABSTRACT: (U) The goal of this project is the study of the electrical breakdown, due to microwaves, which occurs on the surface of vacuum/atmosphere interfaces. This is a final report for AFOSR Grant No. 88-0102, that began in January, 1988. This report, however, will concentrate on the results since the last annual report, dated September 3, 1990. In the past year, the system was fired over 300 times while investigating the breakdown process. Window materials, coatings, surface textures, shapes, and ambient gases were all varied and the results recorded. The diagnostics system was timed to provide temporal correlation between the different signals. Using the particle-in-cell code (MAGIC), overall microwave power and field information has been calculated for the various window configurations. The bulk of these shots were taken using about one-half of the available power from the machine. Recently, the machine was fired several times at near maximum values. Weak points in the machine design were discovered and corrected. Research is continuing, under AFOSR grant No. 91-0260, using the higher power levels from the machine.

ABSTRACT: (U) The techniques of magnetic source imaging (MSI) have been applied to studies of three important aspects of human cognition: (1) An investigation of the effects of selective spatial attention on information processing within the human visual cortex for stimuli of constant luminance have revealed that early response components from 120 to 180 ms latency provide evidence for such effects, but amplitude enhancements for later components from 120 to 180 ms latency provide evidence for such effects, but amplitude enhancements for later components are probably related to pattern recognition and task-relevant stimulus discrimination; (2) A study of the relationship between the performance of a cognitive task such as visual imagery, or silent rhyming, and the suppression of spontaneous cortical rhythms reveals that the location, onset time, and duration of suppression are task specific and correlate with measures of performance; (3) The first characterization of the functional attributes of neuronal activity in human auditory association cortex provides evidence that cortical activation traces in primary and association areas can be accurately characterized by distinct lifetimes, which typically amount to several seconds, and that these sensor memories characterize specific physical attributes of sounds.

UNCLASSIFIED REPORT

ABSTRACT: (U) Biomimicking is now regarded as an area of research in which the analysis of natural materials will provide insights into the design of novel manmade materials, resulting in superior structures able to withstand the requirements placed upon advanced materials. It is well recognized that biological systems efficiently produce complex composites possessing unique properties with greater control than is possible with synthetic materials. Biological materials often have hierarchical structures with unprecedented properties at spatial levels on the molecular, micrometer, and macrometer scales. The dynamism of these systems allows the collection and transport of constituents; the nucleation, configuration, and growth of new structures by self-assembly; and the repair and replacement of old or damaged components. With this in mind, this workshop is intended to identify the most critical issues and to establish future directions for biomimicking in materials science and engineering. The goals of this workshop are to further educate the Air Force participants in the possibilities of biomimetric design and processing and to encourage the research participants to address the interfacing of these possibilities with aerospace needs. Natural materials cannot be used for many aerospace applications because of

UNCLASSIFIED REPORT

ABSTRACT: (U) On January 28-30, 1991, a workshop on
architectures for free-space digital optical computing
was held at the Holiday Inn Chateau Vail in Vail,
Colorado. The workshop was initiated by Alan Craig of the
Air Force Office of Scientific Research and was organized
with Miles Murodocca (Rutgers University) and Michael
Prise (AT and T Bell Labs). The purpose of the workshop
was to bring together a panel of distinguished
contributors to the field, identify current directions
and discuss the future of the field. The emphasis of the
workshop was on overall system architectures. Since
systems depend on devices and optics, a number of
contributors in these areas were invited both to provide
a perspective on implementations and to learn what
additional progress is necessary in order to implement
systems that are either competitive or that complement
future digital electronic systems.

UNCLASSIFIED REPORT

ABSTRACT: (U) Improvements made to the electro-optic sampling system have been instrumental to the demonstration of world record performance of an integrated photodiode/electrical sampler. Measured, underconvolved time response of the circuit was 1.8ps, corresponding to an electrical 3dB bandwidth of 200GHz. To measure such a short time response, the pulse width of the electro-optic sampling system was also used to make the first measurements of broadband electro-optic response of organic polymers. The use of these polymers, as well as erbium doped fiber optical amplifiers, to increase the utility of electro-optic sampling techniques has been investigated. (Author)

ABSTRACT: (U) The objective of this work was to investigate new transition metal silicon complexes as precursors to ceramic materials, or as catalysts for the synthesis of silicon containing polymers. Precursors to metal silicates were based on complexes of the trivalent metal siloxyl ligand. Very low temperature, clean routes to silicate materials were discovered. The ceramic materials that were investigated in most detail had the compositions MO_2SiO_2 ($\text{M} = \text{Ti, Zr, Hf}$). It was shown that these thermolytic methods could be carried out in solution, and used to apply smooth, thin films of the silicate materials. New transition metal silyl complexes were discovered, and some were used in mechanistic studies to demonstrate a mechanism for the metal-catalyzed dehydrocoupling of silanes to polysilanes. This represents a new polymerization mechanism which shows great promise for the synthesis of new polymers.

ABSTRACT: (U) During the period covered by the grant four areas were worked on: (1) Diffuse tomography, (2) Concentrating a signal in the physical and spectral domains, (3) New explicit solutions for the Kadomtsev-Petviashvili equation, and (4) Time and band limiting on the symmetric group.

ABSTRACT: (U) Efforts in this program have focused on developing an understanding of the nature and kinetics of component interactions in hybrid material systems at elevated temperature. Previous work on the chemical interactions in tungsten fiber reinforced superalloys was expanded on to include the effect of matrix chemistry on fiber recrystallization kinetics. General studies to assess the kinetics and diffusion path behavior of metal intermetallic (W/Ni3Al) and intermetallic intermetallic (TiAl/Ni3Al) were also undertaken. A feasibility study for production of diffusion barrier layers via ion implantation were also conducted. In response to a controversy in the scientific community, the influence of fiber matrix interactions on the anomalous creep behavior of SiC/Al was investigated.

ABSTRACT: (U) In the past three years we conducted theoretical and experimental studies of some naturally occurring ionospheric disturbances. Periodic amplitude variations of satellite beacon signals were observed as the precursors of the plumes of equatorial ionospheric irregularities. Some outstanding features of explosive spread F reported in Woodman and La Hoz and Woodman and Kudeki can be reasonably understood in terms of the lightning induced electromagnetic effects. The spectral broadening of monochromatic VLF radio signals detected by satellites in the topside ionospheric was attributed to the nonlinear scattering of waves off ionospheric density irregularities. Furthermore, the irregularity anisotropy can give rise to prominent effects on the Faraday polarization fluctuations of linearly polarized radio signals. This fact can be used to develop the radio diagnostics of the anisotropic nature of ionospheric irregularities, namely, to determine the geometry of field-aligned density irregularities, namely, to determine the geometry of field-aligned density irregularities. Efforts were also made on the reduction of ionospheric effects on the polarization measurements during satellite tracking.

ABSTRACT: (U) The conference that formed the basis for the present volume took place in May, 1990 at the Rensselaerville Institute in Rensselaerville, New York near Albany. This last meeting reflected the increased pace and breadth of recent research. Most important, it added a new theme to the two stressed before: Its central goal was to discuss, in a connected fashion, the entire sequence of events underlying learning and development. Such a comprehensive and logical format has only become possible in the last few years. Before that, knowledge was too fragmentary to permit meaningful adherence to this framework. At the same time, recent advances have made it imperative to encourage interactions between scientists working at each level in this sequence, if understanding of learning and development is not to remain disjointed and compartmentalized. To emphasize this theme, the meeting's organization paralleled the progression from neuronal activity to altered behavior. Thus, the first session described receptor-mediated triggers of plasticity, the second discussed accompanying molecular events, the next two evaluated synaptic modifications resulting from these events, and the last two evaluated expression of these synaptic modifications as altered behavior of neural networks and whole animals.

ABSTRACT: (U) A microcomputer program utilizing molecular connectivity indices (MCI) property, total molecular surface area (TSA) property and property-property correlations and UNIFAC derived activity coefficients, is being developed to provide a fast, economical method to estimate aqueous solubility, octanol/water partition coefficients, vapor pressures, organic carbon, normalized soil sorption coefficients, bioconcentration factors, and Henry's Law constants for use in environmental fate modeling. The structural information for the MCI and UNIFAC models can be input using Simplified Molecular Input Line Entry System (SMILES) notation or connection tables generated from a commercially available two dimensional drawing program. The TSA module accepts 3-D cartesian coordinates entered manually or directly reads coordinate files generated by molecular modeling software. In the MCI, TSA, and Property Property modules, the user can select from either universal or class specific regression models for each property. To aid the user in choosing the most appropriate regression model(s), the program automatically suggests the most appropriate regression model based on the structure of the compound.

UNCLASSIFIED REPORT

ABSTRACT: (U) Inhibition of two-dimensional Tollmien-Schlichting waves by active mean is well known. Surface deformation, heat input and mechanical means were used to impose disturbances on the boundary layer which have an opposite phase to the waves existing in the flow. Thus, transition might be delayed by suppressing the amplitude of these waves. Natural disturbances in boundary layers start as three-dimensional wave packets, because they originate at surface imperfections or are precipitated by temporal disturbances in the incoming stream. The possibilities of controlling such disturbances are currently being investigated. In this context the spatial interaction among three dimensional wave trains, emanating from discrete point-sources, in a boundary layer are discussed. Only a local wave attenuation is feasible by activating two harmonic point-source disturbances anywhere in the boundary layer. This was shown theoretically for a variety of locations, separation distances and phase delays between the two source and proven experimentally when the disturbance sources were displaced along the span. The spanwise phase gradients of the disturbances, linked to the streamwise distance from their point-source present a major obstacle to such a simple attenuation scheme. These difficulties

AD-A243 727

AD-A243 727

UNCLASSIFIED

PAGE 224

T85004

cannot be foreseen by considering 3-D perturbations. Spatially distributed control mechanisms are therefore required for the purpose of delaying the amplification of concentrated three-dimensional disturbances.

ABSTRACT: (U) We have studied grid-generated turbulence in a water tunnel at moderate Reynolds numbers. The method used was the standard one of Laser Doppler Velocimetry (LDV) and novel scheme, which we call photon homodyne correlation spectroscopy(HCS). With LDV, we measured the probability density function of velocity differences $P(\Delta v(t))$ on varying spatial scales l , by invoking the frozen turbulence hypothesis. The HCS technique permits measuring P without using this hypothesis. Of special interest to us was the behavior of the system at and above a Reynolds number (Re sub c) where the turbulence becomes self-similar, in that (Δv) (1 sq) $>$ approx. 1 to the zeta power. Above Re sub c the exponent zeta increases from 0 to 2/3 with increasing Re .

ABSTRACT: (U) The objective of this research program has been the development of new materials with enhanced nonlinear optical activity and the exploration of related properties such as electrical conductivity. Initial research efforts focused upon pi-electron materials (polyenes and heteroaromatic polymers) and synthetic routes for overcoming the inherent insolubility of these materials. By steadily improving solubility and processability through utilization of derivation and precursor routes, we have been able to fabricate optical quality films of ladder-type polymers and achieve high resolution characterization of these materials both in terms of structure and electroactive properties. Electroactive molecules including fused ring (ladder oligomers) dyes, squarylium-heterocyclic moieties, phenylpolyenes, thienylpolyenes, carbocyanine dyes, and tetraazaannulenes have also been synthetically incorporated into a variety of traditional polymers both as pendants and as part of the polymer backbone.

for vision computations continues to be the focus of
research. Additionally, some further testing of a three
layer back propagation learning network for computing
slat tilt was undertaken. A model has been developed
which simulates the process of texture segmentation in
the visual cortex according to the computational model of
M.R. Turner et.al. using the McGregor high fidelity
neural simulator. This system attempts to faithfully
simulate the transfer functions of neurons using various
numerical simulation methods.

UNCLASSIFIED REPORT

ABSTRACT: (U) The research conducted during the one year funding period was a subset of the original three year study of the perception of complex auditory patterns, including speech and music. One set of experiments explored two early stages in the perception of complex signals, using adaptation procedures. This research investigated effects of varying signal amplitude, and the effects of more cognitive factors: lexical knowledge, and the listener's level of attention to the adapting sound. A second set of experiments investigated how knowledge of particular words influenced the perceptual restoration of deleted or degraded portions of the word. The two lines of research represent progress toward understanding the analyses conducted on complex auditory patterns by human listeners.

ABSTRACT: (U) Many sounds of ecological importance consist of complex acoustic patterns, and the research conducted during the previous grant has dealt with some of the rules and mechanisms governing the perception of such sounds. (1) Using randomly derived waveforms (frozen noise segments) as model long-period complex sounds, a series of experiments examined aspects of the stimuli used for recognition, and tested hypotheses concerning the basic principles governing the perception of these sounds. (2) New evidence was reported indicating that sequences of brief tones and brief vowels are perceived as global patterns or temporal compounds. Different arrangements of component sounds from distinctive compounds, so that permuted orders can be discriminated without resolution into component elements. The same basic rules govern the perception of frozen noises, sequences of tones, and sequences of vowels, with overlays of special rules for melodic and phonetic sequences.

ABSTRACT: (U) Purified ADPRT protein was inactivated by the histidine specific reagent diethylpyrocarbonate, binding to two histidine residues, or by a relatively histidine selective photoinactivation method. Inactivation with up to 1.3 mM diethylpyrocarbonate was reversible by hydroxylamine. Enzymatic inactivation coincided with the loss of binding capacity of the enzyme protein to benzamide affinity matrix but not to deoxyribonucleic acid cellulose. Labelled diethylpyrocarbonate was identified exclusively in the 56 kDa carboxyl-terminal polypeptide where 2 out of 13 histidine residues were modified by this reagent. It is proposed that histidine residues in the 56 kDa polypeptide may participate as initiator sites for poly ADP-ribosylation.

ABSTRACT: (U) The properties of blends of two polyquinolines and block copolymers of the same polymers have been studied as the basis for a molecular composite. The polyquinolines differ only in the presence or absence of an oxygen atom in the chain backbone. The chain conformation is found to be extended, with a persistence length of 20 nm without the oxygen linkage. The chain adopts a flexible conformation when the oxygen is present. Both forms, and their copolymer, were synthesized in this study. The results show that although the thermodynamically expected phase separation can be partially frustrated in the preparation of blends of the two polymers, the enhanced mobility at the elevated temperatures needed for processing the solid blend leads to substantial phase separation, with consequent deterioration of mechanical properties.

UNCLASSIFIED REPORT

ABSTRACT: (U) Many chemical and physical changes depend on the transfer of energy that occurs in an encounter between molecules. In recent years, new sophisticated experimental and theoretical techniques have addressed fundamental questions of energy transfer between individual quantum states in bimolecular collisions. Many processes are found to be state-specific, and the effects of different forms of energy are not equivalent. For example, some chemical reactions may be promoted more by vibrational than translational energy, or vice versa, and electronic state transfer may be more affected by rotation than by vibration. From a more applied standpoint, we are unable to predict details of energy transfer that might be needed to model the behavior of some practical system, outside the immediate regime of prior measurements.

ABSTRACT: (U) For the embryolethality tests, semicarbazide and isoniazid showed a slightly less than additive embryolethal response. Potentially different lethal modes of action may be observed for compounds that are thought to be teratogenic by the same mode of action. For the embryolethal binary mixture test of hydroxyurea and isoniazid the 3:1 mixture showed an antagonistic response, while the 1:1 and 1:3 mixtures were response additive, as expected. The antagonistic response may have been the result of poorer absorption of hydroxyurea by the severely malformed embryos, as isoniazid had a much greater concentration (in mg/L) than did hydroxyurea, even though the effective (lethal) concentration for hydroxyurea was nearly three times that for isoniazid. Short-chain carboxylic acids showed concentration additive joint actions for induction of malformation. Combinations of DNA synthesis inhibitors showed response additive to antagonistic joint actions as malformation-inducing concentration.

UNCLASSIFIED REPORT

ABSTRACT: (U) This thesis is an experimental investigation of the passive scalar (species concentration) field in the far-field of round, axisymmetric, high Schmidt number (liquid phase), turbulent jets issuing into a quiescent reservoir, by means of a quantitative laser-induced fluorescence technique. Single-point concentration measurements are made on the jet centerline, at axial locations from 100 to 305 nozzle diameters downstream, and Reynolds numbers of 3,000 to 102,000, yielding data with a resolved temporal dynamic range up to 2.5×10 to the 5th power, and capturing as many as 504 large-scale structure passages. Long-time statistics of the jet concentration are found to converge slowly. Between 100 and 300 large-scale structure passages are required to reduce the uncertainty in the mean to 1%, or so. The behavior of the jet varies with Reynolds number. The centerline concentration pdf's become taller and narrower with increasing Re, and the normalized concentration variances correspondingly decrease with Re. The concentration power spectra also evolve with Re. The behavior of the spectral slopes is examined. No constant -1 (Batchelor) spectral slope range is present. Rather, in the viscous region, the power spectra exhibit log-normal behavior, over a range of scales exceeding a factor of 40, in some cases.

UNCLASSIFIED REPORT

ABSTRACT: (U) Some experimental data on turbulent free-shear-layer growth, mixing, and chemical reactions are reviewed. The dependence of these phenomena on such fluid and flow parameters as Reynolds number, Schmidt number, and Mach number are discussed, with the aid of some direct consequences deducible from the large-scale organization of the flow as well as from some recent models. The mixing of two or more fluids that are entrained into a turbulent region is an important process from both a scientific and an applications vantage point. Species can be transported by turbulence to produce a more uniform distribution than some initial mean profile. This process is sometimes also referred to as mixing, without regard to whether the transported species are mixed on a molecular scale or not. If the issue of mixing arises in the context of chemical reactions and combustion, however, we recognize that only fluid mixed on a molecular scale can contribute to chemical product formation and associated heat release. The discussion in this paper will be limited to molecular mixing.

ABSTRACT: (U) The overall goal of this research project is to systematically investigate a number of the possible ways through which presynaptic modulation might influence the effectiveness of local synaptic interactions at the mammalian hippocampal mossy fiber synapse. A hippocampal subcellular fraction that is highly enriched in large mossy fiber nerve endings was developed for this purpose. The morphological and metabolic properties of this synaptosomal preparation have previously been described, and both glutamate and prodynorphin derived peptides have been shown to be released from these specialized nerve endings in response to membrane depolarization by calcium-dependent mechanisms. During the first year of this research project, it was demonstrated that distinct types of voltage-gated calcium channels are required for the exocytosis of glutamate and dynorphin peptides.

UNCLASSIFIED REPORT

ABSTRACT: (U) Organ specific distribution of carboxylesterases (Western blotting) was determined to be liver lung = testes = fat pancreas kidney. Carboxylesterase distribution among cell types of the testes was examined by in situ hybridization techniques. Results were inconclusive, as both the probe and the control hybridized to tissues macromolecules. More refinement of this techniques should provide better results. Other accomplishments include examination of the down-regulation of carboxylesterase levels by glucocorticoids. Apparently esterase levels are most dramatically down-regulated (approximately 6-fold) by dexamethasone phosphate (80 mg/kg x 5 days, i.p.) in the testes compared to the other tissues containing this enzyme.
